2	Quick Start	5
3	Schema Model	7
4	Informative Errors	9
5	Contributing	11
6	Issues	13
7	Need Help? 7.1 DataFrame Schemas 7.1.1 Column Validation 7.1.1.1 Null Values in Columns 7.1.1.2 Coercing Types on Columns 7.1.1.3 Required Columns 7.1.1.4 Ordered Columns 7.1.1.5 Stand-alone Column Validation 7.1.1.6 Column Regex Pattern Matching 7.1.1.7 Handling Dataframe Columns not in the Schema 7.1.1.8 Validating the order of the columns 7.1.1.9 Validating the joint uniqueness of columns 7.1.2 Index Validation 7.1.3 MultiIndex Validation 7.1.3.1 MultiIndex Columns 7.1.3.2 MultiIndex Indexes 7.1.4 Get Pandas Data Types 7.1.5 DataFrameSchema Transformations 7.2 Schema Models 7.2.1 Basic Usage 7.2.2 Validate on Initialization 7.2.3 Converting to DataFrameSchema 7.2.4 Excluded attributes 7.2.5 Supported dtypes	15 16 16 17 18 19 19 21 22 22 23 24 24 24 25 26 28 29 30 31
	7.2.5 Supported dtypes 7.2.5.1 Dtype aliases 7.2.5.2 Type Vs instance 7.2.5.3 Parametrized dtypes 7.2.5.3.1 Annotated	31 31 31 32 32

	7.2.5.3.2 Field	33
	7.2.6 Required Columns	33
	7.2.7 Schema Inheritance	34
	7.2.8 Config	34
	7.2.9 MultiIndex	35
	7.2.10 Custom Checks	36
	7.2.10.1 Column/Index checks	36
	7.2.10.2 DataFrame Checks	37
	7.2.10.3 Inheritance	37
	7.2.11 Aliases	38
7.3	Series Schemas	40
7.4	Checks	40
	7.4.1 Checking column properties	40
	7.4.2 Built-in Checks	41
	7.4.3 Vectorized vs. Element-wise Checks	41
	7.4.4 Handling Null Values	42
	7.4.5 Column Check Groups	42
	7.4.6 Wide Checks	43
	7.4.7 Raise UserWarning on Check Failure	44
	7.4.8 Registering Custom Checks	45
7.5	Hypothesis Testing	45
1.5		45
		47
7.6	71	47
7.0	Pandera Data Types	48
	7.6.1 Motivations	
	7.6.2 DataType basics	49
	7.6.3 Example	49
	7.6.4 Parametrized data types	51
	7.6.5 Defining the coerce_value method	51
7.7	Decorators for Pipeline Integration	51
	7.7.1 Check Input	52
	7.7.2 Check Output	53
	7.7.3 Check IO	54
	7.7.4 Decorate Functions and Coroutines	54
7.8	Schema Inference	55
	7.8.1 Schema Persistence	56
	7.8.1.1 Write to a Python script	56
	7.8.1.2 Write to YAML	58
7.9	Lazy Validation	59
7.10	Data Synthesis Strategies	62
	7.10.1 Basic Usage	62
	7.10.2 Usage in Unit Tests	62
	7.10.3 Strategies and Examples from Schema Models	63
	7.10.4 Checks as Constraints	63
	7.10.4.1 Check Strategy Chaining	64
	7.10.4.2 In-line Custom Checks	64
	7.10.5 Defining Custom Strategies	65
7.11	Extensions	65
	7.11.1 Registering Custom Check Methods	65
	7.11.2 Specifying a Check Strategy	66
	7.11.3 Check Types	67
	7.11.3.1 Element-wise Checks	67
	7.11.3.2 Groupby Checks	67
	7.11.4 Registered Custom Checks with the Class-based API	68

7.12	Data Format Conversion	70 70
	7.12.2 Takeaway	72
7.13	Supported DataFrame Libraries	72
	7.13.1 Domain-specific Data Validation	72
	7.13.1.1 Data Validation with GeoPandas	72
	7.13.2 Scaling Up Data Validation	74
	7.13.2.1 Data Validation with Dask	74
	7.13.2.2 Data Validation with Fugue	76
	7.13.2.2.1 What is Fugue?	76
	7.13.2.2.2 Example	76
	7.13.2.2.3 Validation by Partition	77
	7.13.2.3 Data Validation with Koalas	79
	7.13.2.4 Data Validation with Pyspark (New)	79
	7.13.2.5 Data Validation with Modin	80
7.14		82

A data validation library for scientists, engineers, and analysts seeking correctness.

pandera provides a flexible and expressive API for performing data validation on dataframes to make data processing pipelines more readable and robust.

Dataframes contain information that pandera explicitly validates at runtime. This is useful in production-critical data pipelines or reproducible research settings. With pandera, you can:

- 1. Define a schema once and use it to validate *different dataframe types* including pandas, dask, modin, and pyspark.pandas.
- 2. Check the types and properties of columns in a pd.DataFrame or values in a pd.Series.
- 3. Perform more complex statistical validation like hypothesis testing.
- 4. Seamlessly integrate with existing data analysis/processing pipelines via function decorators.
- 5. Define schema models with the *class-based API* with pydantic-style syntax and validate dataframes using the typing syntax.
- 6. Synthesize data from schema objects for property-based testing with pandas data structures.
- 7. Lazily Validate dataframes so that all validation rules are executed before raising an error.
- 8. Integrate with a rich ecosystem of python tools like pydantic, fastapi and mypy.

INTRODUCTION 1

2 INTRODUCTION

ONE

INSTALL

Install with pip:

```
pip install pandera
```

Or conda:

```
conda install -c conda-forge pandera
```

1.1 Extras

Installing additional functionality:

pip

```
pip install pandera[hypotheses]
                                 # hypothesis checks
pip install pandera[io]
                                 # yaml/script schema io utilities
pip install pandera[strategies] # data synthesis strategies
                                 # enable static type-linting of pandas
pip install pandera[mypy]
pip install pandera[dask]
                                 # validate dask dataframes
                                 # validate pyspark dataframes
pip install pandera[pyspark]
pip install pandera[modin]
                                 # validate modin dataframes
                                 # validate modin dataframes with ray
pip install pandera[modin-ray]
pip install pandera[modin-dask] # validate modin dataframes with dask
pip install pandera[geopandas]
                                 # validate geopandas geodataframes
```

conda

```
conda install -c conda-forge pandera-hypotheses
                                                 # hypothesis checks
conda install -c conda-forge pandera-io
                                                 # yaml/script schema io utilities
conda install -c conda-forge pandera-strategies
                                                 # data synthesis strategies
                                                 # enable static type-linting of pandas
conda install -c conda-forge pandera-mypy
conda install -c conda-forge pandera-fastapi
                                                 # fastapi integration
                                                 # validate dask dataframes
conda install -c conda-forge pandera-dask
conda install -c conda-forge pandera-pyspark
                                                 # validate pyspark dataframes
conda install -c conda-forge pandera-modin
                                                 # validate modin dataframes
                                                 # validate modin dataframes with ray
conda install -c conda-forge pandera-modin-ray
conda install -c conda-forge pandera-modin-dask # validate modin dataframes with dask
```

4 Chapter 1. Install

TWO

QUICK START

```
import pandas as pd
import pandera as pa
# data to validate
df = pd.DataFrame({
    "column1": [1, 4, 0, 10, 9],
    "column2": [-1.3, -1.4, -2.9, -10.1, -20.4],
    "column3": ["value_1", "value_2", "value_3", "value_2", "value_1"],
})
# define schema
schema = pa.DataFrameSchema({
    "column1": pa.Column(int, checks=pa.Check.le(10)),
    "column2": pa.Column(float, checks=pa.Check.lt(-1.2)),
   "column3": pa.Column(str, checks=[
       pa.Check.str_startswith("value_"),
        # define custom checks as functions that take a series as input and
        # outputs a boolean or boolean Series
       pa.Check(lambda s: s.str.split("_", expand=True).shape[1] == 2)
   ]),
})
validated_df = schema(df)
print(validated_df)
```

```
column1 column2 column3
        1
              -1.3 value_1
0
1
        4
              -1.4 value_2
2
              -2.9 value_3
        0
3
             -10.1 value_2
        10
4
        9
             -20.4 value 1
```

You can pass the built-in python types that are supported by pandas, or strings representing the legal pandas datatypes, or pandera's DataType:

```
schema = pa.DataFrameSchema({
    # built-in python types
    "int_column": pa.Column(int),
    "float_column": pa.Column(float),
    "str_column": pa.Column(str),
```

(continues on next page)

(continued from previous page)

```
# pandas dtype string aliases
"int_column2": pa.Column("int64"),
"float_column2": pa.Column("float64"),
# pandas > 1.0.0 support native "string" type
"str_column2": pa.Column("str"),

# pandera DataType
"int_column3": pa.Column(pa.Int),
"float_column3": pa.Column(pa.Float),
"str_column3": pa.Column(pa.String),
})
```

For more details on data types, see *DataType*

THREE

SCHEMA MODEL

pandera also provides an alternative API for expressing schemas inspired by dataclasses and pydantic. The equivalent <code>SchemaModel</code> for the above <code>DataFrameSchema</code> would be:

```
from pandera.typing import Series

class Schema(pa.SchemaModel):

    column1: Series[int] = pa.Field(le=10)
        column2: Series[float] = pa.Field(lt=-1.2)
        column3: Series[str] = pa.Field(str_startswith="value_")

    @pa.check("column3")
    def column_3_check(cls, series: Series[str]) -> Series[bool]:
        """Check that column3 values have two elements after being split with '_"""
        return series.str.split("_", expand=True).shape[1] == 2

Schema.validate(df)
```

FOUR

INFORMATIVE ERRORS

If the dataframe does not pass validation checks, pandera provides useful error messages. An error argument can also be supplied to Check for custom error messages.

In the case that a validation Check is violated:

```
Traceback (most recent call last):
...
SchemaError: <Schema Column: 'column1' type=<class 'int'>> failed element-wise validator

-0:
<Check <lambda>: range checker [0, 10]>
failure cases:
  index failure_case
0     0     -20
1     3     30
```

And in the case of a mis-specified column name:

```
# column name mis-specified
wrong_column_df = pd.DataFrame({
    "foo": ["bar"] * 10,
    "baz": [1] * 10
})
simple_schema.validate(wrong_column_df)
```

```
Traceback (most recent call last):
...
pandera.SchemaError: column 'column1' not in dataframe
foo baz
0 bar 1
1 bar 1
2 bar 1
3 bar 1
4 bar 1
```

FIVE

CONTRIBUTING

All contributions, bug reports, bug fixes, documentation improvements, enhancements and ideas are welcome.

A detailed overview on how to contribute can be found in the contributing guide on GitHub.

CHAPTER
SIX

ISSUES

Submit issues, feature requests or bugfixes on github.

14 Chapter 6. Issues

NEED HELP?

There are many ways of getting help with your questions. You can ask a question on Github Discussions page or reach out to the maintainers and pandera community on Discord

7.1 DataFrame Schemas

The <code>DataFrameSchema</code> class enables the specification of a schema that verifies the columns and index of a pandas <code>DataFrame</code> object.

The DataFrameSchema object consists of Columns and an Index.

```
import pandera as pa
from pandera import Column, DataFrameSchema, Check, Index
schema = DataFrameSchema(
    {
        "column1": Column(int),
        "column2": Column(float, Check(lambda s: s < -1.2)),</pre>
        # you can provide a list of validators
        "column3": Column(str, [
           Check(lambda s: s.str.startswith("value")),
           Check(lambda s: s.str.split("_", expand=True).shape[1] == 2)
        ]),
    },
    index=Index(int),
    strict=True,
    coerce=True,
)
```

You can refer to *Schema Models* to see how to define dataframe schemas using the alternative pydantic/dataclass-style syntax.

7.1.1 Column Validation

A *Column* must specify the properties of a column in a dataframe object. It can be optionally verified for its data type, *null values* or duplicate values. The column can be *coerced* into the specified type, and the *required* parameter allows control over whether or not the column is allowed to be missing.

Similarly to pandas, the data type can be specified as:

- a string alias, as long as it is recognized by pandas.
- a python type: int, float, double, bool, str
- a numpy data type
- a pandas extension type: it can be an instance (e.g pd.CategoricalDtype(["a", "b"])) or a class (e.g pandas.CategoricalDtype) if it can be initialized with default values.
- a pandera DataType: it can also be an instance or a class.

Column checks allow for the DataFrame's values to be checked against a user-provided function. Check objects also support *grouping* by a different column so that the user can make assertions about subsets of the column of interest.

Column Hypotheses enable you to perform statistical hypothesis tests on a DataFrame in either wide or tidy format. See *Hypothesis Testing* for more details.

7.1.1.1 Null Values in Columns

By default, SeriesSchema/Column objects assume that values are not nullable. In order to accept null values, you need to explicitly specify nullable=True, or else you'll get an error.

```
import numpy as np
import pandas as pd
import pandera as pa

from pandera import Check, Column, DataFrameSchema

df = pd.DataFrame({"column1": [5, 1, np.nan]})

non_null_schema = DataFrameSchema({
    "column1": Column(float, Check(lambda x: x > 0))
})

non_null_schema.validate(df)
```

```
Traceback (most recent call last):
...
SchemaError: non-nullable series contains null values: {2: nan}
```

```
null_schema = DataFrameSchema({
    "column1": Column(float, Check(lambda x: x > 0), nullable=True)
})
print(null_schema.validate(df))
```

```
column1
0 5.0
1 1.0
2 NaN
```

7.1.1.2 Coercing Types on Columns

If you specify Column(dtype, ..., coerce=True) as part of the DataFrameSchema definition, calling schema. validate will first coerce the column into the specified dtype before applying validation checks.

```
import pandas as pd
import pandera as pa

from pandera import Column, DataFrameSchema

df = pd.DataFrame({"column1": [1, 2, 3]})
    schema = DataFrameSchema({"column1": Column(str, coerce=True)})

validated_df = schema.validate(df)
    assert isinstance(validated_df.column1.iloc[0], str)
```

Note: Note the special case of integers columns not supporting nan values. In this case, schema.validate will complain if coerce == True and null values are allowed in the column.

```
df = pd.DataFrame({"column1": [1., 2., 3, np.nan]})
schema = DataFrameSchema({
    "column1": Column(int, coerce=True, nullable=True)
})
validated_df = schema.validate(df)
```

```
Traceback (most recent call last):
...
pandera.errors.SchemaError: Error while coercing 'column1' to type int64: Cannot convert

non-finite values (NA or inf) to integer
```

The best way to handle this case is to simply specify the column as a Float or Object.

```
schema_object = DataFrameSchema({
    "column1": Column(object, coerce=True, nullable=True)
})
schema_float = DataFrameSchema({
    "column1": Column(float, coerce=True, nullable=True)
})
print(schema_object.validate(df).dtypes)
print(schema_float.validate(df).dtypes)
```

```
column1 object
dtype: object
```

(continues on next page)

(continued from previous page)

```
column1 float64
dtype: object
```

If you want to coerce all of the columns specified in the DataFrameSchema, you can specify the coerce argument with DataFrameSchema(..., coerce=True).

7.1.1.3 Required Columns

By default all columns specified in the schema are required, meaning that if a column is missing in the input DataFrame an exception will be thrown. If you want to make a column optional, specify required=False in the column constructor:

```
import pandas as pd
import pandera as pa

from pandera import Column, DataFrameSchema

df = pd.DataFrame({"column2": ["hello", "pandera"]})
schema = DataFrameSchema({
    "column1": Column(int, required=False),
    "column2": Column(str)
})

validated_df = schema.validate(df)
print(validated_df)
```

```
column2
0 hello
1 pandera
```

Since required=True by default, missing columns would raise an error:

```
schema = DataFrameSchema({
    "column1": Column(int),
    "column2": Column(str),
})
schema.validate(df)
```

```
Traceback (most recent call last):
...
pandera.SchemaError: column 'column1' not in dataframe
   column2
0 hello
1 pandera
```

7.1.1.4 Ordered Columns

7.1.1.5 Stand-alone Column Validation

In addition to being used in the context of a DataFrameSchema, Column objects can also be used to validate columns in a dataframe on its own:

```
import pandas as pd
import pandera as pa
df = pd.DataFrame({
    "column1": [1, 2, 3],
   "column2": ["a", "b", "c"],
})
column1_schema = pa.Column(int, name="column1")
column2_schema = pa.Column(str, name="column2")
# pass the dataframe as an argument to the Column object callable
df = column1_schema(df)
validated_df = column2_schema(df)
# or explicitly use the validate method
df = column1_schema.validate(df)
validated_df = column2_schema.validate(df)
# use the DataFrame.pipe method to validate two columns
validated_df = df.pipe(column1_schema).pipe(column2_schema)
```

For multi-column use cases, the *DataFrameSchema* is still recommended, but if you have one or a small number of columns to verify, using Column objects by themselves is appropriate.

7.1.1.6 Column Regex Pattern Matching

In the case that your dataframe has multiple columns that share common statistical properties, you might want to specify a regex pattern that matches a set of meaningfully grouped columns that have str names.

```
import numpy as np
import pandas as pd
import pandera as pa

categories = ["A", "B", "C"]

np.random.seed(100)

dataframe = pd.DataFrame({
    "cat_var_1": np.random.choice(categories, size=100),
    "cat_var_2": np.random.choice(categories, size=100),
    "num_var_1": np.random.uniform(0, 10, size=100),
    "num_var_2": np.random.uniform(20, 30, size=100),
})

schema = pa.DataFrameSchema({
```

(continues on next page)

(continued from previous page)

```
"num_var_.+": pa.Column(
    float,
    checks=pa.Check.greater_than_or_equal_to(0),
    regex=True,
),
"cat_var_.+": pa.Column(
    pa.Category,
    checks=pa.Check.isin(categories),
    coerce=True,
    regex=True,
),
})
print(schema.validate(dataframe).head())
```

```
cat_var_1 cat_var_2 num_var_1 num_var_2
         Α
                   Α
                     6.804147 24.743304
1
         Α
                   C
                       3.684308 22.774633
                       5.911288 28.416588
2
                   C
         Α
3
         C
                   Α
                      4.790627 21.951250
         C
4
                      4.504166 28.563142
```

You can also regex pattern match on pd.MultiIndex columns:

```
np.random.seed(100)
dataframe = pd.DataFrame({
    ("cat_var_1", "y1"): np.random.choice(categories, size=100),
    ("cat_var_2", "y2"): np.random.choice(categories, size=100),
    ("num_var_1", "x1"): np.random.uniform(0, 10, size=100),
    ("num_var_2", "x2"): np.random.uniform(0, 10, size=100),
})
schema = pa.DataFrameSchema({
    ("num_var_.+", "x.+"): pa.Column(
        checks=pa.Check.greater_than_or_equal_to(0),
        regex=True,
   ),
    ("cat_var_.+", "y.+"): pa.Column(
        pa.Category,
        checks=pa.Check.isin(categories),
        coerce=True,
        regex=True,
   ),
})
print(schema.validate(dataframe).head())
```

```
    cat_var_1 cat_var_2 num_var_1 num_var_2

    y1
    y2
    x1
    x2

    0
    A
    A 6.804147 4.743304
```

(continues on next page)

(continued from previous page)

```
      1
      A
      C
      3.684308
      2.774633

      2
      A
      C
      5.911288
      8.416588

      3
      C
      A
      4.790627
      1.951250

      4
      C
      B
      4.504166
      8.563142
```

7.1.1.7 Handling Dataframe Columns not in the Schema

By default, columns that aren't specified in the schema aren't checked. If you want to check that the DataFrame *only* contains columns in the schema, specify strict=True:

```
Traceback (most recent call last):
...
SchemaError: column 'column2' not in DataFrameSchema {'column1': <Schema Column: 'None'_
__type=DataType(int64)>}
```

Alternatively, if your DataFrame contains columns that are not in the schema, and you would like these to be dropped on validation, you can specify strict='filter'.

```
import pandas as pd
import pandera as pa

from pandera import Column, DataFrameSchema

df = pd.DataFrame({"column1": ["drop", "me"],"column2": ["keep", "me"]})
    schema = DataFrameSchema({"column2": Column(str)}, strict='filter')

validated_df = schema.validate(df)
print(validated_df)
```

```
column2
0 keep
1 me
```

7.1.1.8 Validating the order of the columns

For some applications the order of the columns is important. For example:

- If you want to use selection by position instead of the more common selection by label.
- Machine learning: Many ML libraries will cast a Dataframe to numpy arrays, for which order becomes crucial.

To validate the order of the Dataframe columns, specify ordered=True:

```
import pandas as pd
import pandera as pa

schema = pa.DataFrameSchema(
    columns={"a": pa.Column(int), "b": pa.Column(int)}, ordered=True
)
df = pd.DataFrame({"b": [1], "a": [1]})
print(schema.validate(df))
```

```
Traceback (most recent call last):
...
SchemaError: column 'b' out-of-order
```

7.1.1.9 Validating the joint uniqueness of columns

In some cases you might want to ensure that a group of columns are unique:

```
import pandas as pd
import pandera as pa

schema = pa.DataFrameSchema(
    columns={col: pa.Column(int) for col in ["a", "b", "c"]},
    unique=["a", "c"],
)
df = pd.DataFrame.from_records([
    {"a": 1, "b": 2, "c": 3},
    {"a": 1, "b": 2, "c": 3},
])
schema.validate(df)
```

7.1.2 Index Validation

You can also specify an Index in the DataFrameSchema.

```
import pandas as pd
import pandera as pa

from pandera import Column, DataFrameSchema, Index, Check

schema = DataFrameSchema(
    columns={"a": Column(int)},
    index=Index(
        str,
        Check(lambda x: x.str.startswith("index_"))))

df = pd.DataFrame(
    data={"a": [1, 2, 3]},
    index=["index_1", "index_2", "index_3"])

print(schema.validate(df))
```

```
a
index_1 1
index_2 2
index_3 3
```

In the case that the DataFrame index doesn't pass the Check.

```
df = pd.DataFrame(
    data={"a": [1, 2, 3]},
    index=["foo1", "foo2", "foo3"])
schema.validate(df)
```

7.1.3 MultiIndex Validation

pandera also supports multi-index column and index validation.

7.1.3.1 MultiIndex Columns

Specifying multi-index columns follows the pandas syntax of specifying tuples for each level in the index hierarchy:

```
import pandas as pd
import pandera as pa

from pandera import Column, DataFrameSchema, Index

schema = DataFrameSchema({
    ("foo", "bar"): Column(int),
        ("foo", "baz"): Column(str)
})

df = pd.DataFrame({
    ("foo", "bar"): [1, 2, 3],
        ("foo", "baz"): ["a", "b", "c"],
})

print(schema.validate(df))
```

```
foo bar baz

0 1 a
1 2 b
2 3 c
```

7.1.3.2 MultiIndex Indexes

The MultiIndex class allows you to define multi-index indexes by composing a list of pandera. Index objects.

```
data={"column1": [1, 2, 3]},
  index=pd.MultiIndex.from_arrays(
       [["foo", "bar", "foo"], [0, 1,2]],
      names=["index0", "index1"]
  )
)
print(schema.validate(df))
```

```
column1
index0 index1
foo 0 1
bar 1 2
foo 2 3
```

7.1.4 Get Pandas Data Types

Pandas provides a *dtype* parameter for casting a dataframe to a specific dtype schema. *DataFrameSchema* provides a dtypes property which returns a dictionary whose keys are column names and values are *DataType*.

Some examples of where this can be provided to pandas are:

- $\bullet\ https://pandas.pydata.org/pandas-docs/stable/reference/api/pandas.read_csv.html$
- https://pandas.pydata.org/pandas-docs/stable/reference/api/pandas.DataFrame.astype.html

```
import pandas as pd
import pandera as pa
schema = pa.DataFrameSchema(
   columns={
      "column1": pa.Column(int),
      "column2": pa.Column(pa.Category),
      "column3": pa.Column(bool)
   },
)
df = (
   pd.DataFrame.from_dict(
            "a": {"column1": 1, "column2": "valueA", "column3": True},
            "b": {"column1": 1, "column2": "valueB", "column3": True},
        },
        orient="index",
   )
    .astype({col: str(dtype) for col, dtype in schema.dtypes.items()})
    .sort_index(axis=1)
)
print(schema.validate(df))
```

```
column1 column2 column3
a 1 valueA True
b 1 valueB True
```

7.1.5 DataFrameSchema Transformations

Once you've defined a schema, you can then make modifications to it, both on the schema level – such as adding or removing columns and setting or resetting the index – or on the column level – such as changing the data type or checks.

This is useful for re-using schema objects in a data pipeline when additional computation has been done on a dataframe, where the column objects may have changed or perhaps where additional checks may be required.

```
import pandas as pd
import pandera as pa
data = pd.DataFrame({"col1": range(1, 6)})
schema = pa.DataFrameSchema(
   columns={"col1": pa.Column(int, pa.Check(lambda s: s >= 0))},
    strict=True)
transformed_schema = schema.add_columns({
    "col2": pa.Column(str, pa.Check(lambda s: s == "value")),
    "col3": pa.Column(float, pa.Check(lambda x: x == 0.0)),
})
# validate original data
data = schema.validate(data)
# transformation
transformed_data = data.assign(col2="value", col3=0.0)
# validate transformed data
print(transformed_schema.validate(transformed_data))
```

```
col1
         col2 col3
0
     1 value
                0.0
        value
1
                 0.0
2
      3 value
                 0.0
3
      4 value
                 0.0
4
      5 value
                 0.0
```

Similarly, if you want dropped columns to be explicitly validated in a data pipeline:

```
import pandera as pa

schema = pa.DataFrameSchema(
    columns={
        "col1": pa.Column(int, pa.Check(lambda s: s >= 0)),
        "col2": pa.Column(str, pa.Check(lambda x: x <= 0)),
        "col3": pa.Column(object, pa.Check(lambda x: x == 0)),
    },</pre>
```

```
strict=True,
)
new_schema = schema.remove_columns(["col2", "col3"])
print(new_schema)
```

```
<Schema DataFrameSchema(
    columns={
        'coll': <Schema Column(name=col1, type=DataType(int64))>
    },
    checks=[],
    coerce=False,
    dtype=None,
    index=None,
    strict=True
    name=None,
    ordered=False,
    unique_column_names=False
)>
```

If during the course of a data pipeline one of your columns is moved into the index, you can simply update the initial input schema using the $set_index()$ method to create a schema for the pipeline output.

```
name=None,
    ordered=True
)>,
    strict=True
name=None,
ordered=False,
unique_column_names=False
)>
```

The available methods for altering the schema are: add_columns(), remove_columns(), update_columns(), rename_columns(), set_index(), and reset_index().

7.2 Schema Models

new in 0.5.0

pandera provides a class-based API that's heavily inspired by pydantic. In contrast to the *object-based API*, you can define schema models in much the same way you'd define pydantic models.

Schema Models are annotated with the pandera.typing module using the standard typing syntax. Models can be explictly converted to a DataFrameSchema or used to validate a DataFrame directly.

Note: Due to current limitations in the pandas library (see discussion here), pandera annotations are only used for **run-time** validation and **cannot** be leveraged by static-type checkers like mypy. See the discussion here for more details.

7.2.1 Basic Usage

```
import pandas as pd
import pandera as pa
from pandera.typing import Index, DataFrame, Series

class InputSchema(pa.SchemaModel):
    year: Series[int] = pa.Field(gt=2000, coerce=True)
    month: Series[int] = pa.Field(ge=1, le=12, coerce=True)
    day: Series[int] = pa.Field(ge=0, le=365, coerce=True)

class OutputSchema(InputSchema):
    revenue: Series[float]

@pa.check_types
def transform(df: DataFrame[InputSchema]) -> DataFrame[OutputSchema]:
    return df.assign(revenue=100.0)

df = pd.DataFrame({
    "year": ["2001", "2002", "2003"],
    "month": ["3", "6", "12"],
```

```
"day": ["200", "156", "365"],
})

transform(df)

invalid_df = pd.DataFrame({
    "year": ["2001", "2002", "1999"],
    "month": ["3", "6", "12"],
    "day": ["200", "156", "365"],
})
transform(invalid_df)
```

```
Traceback (most recent call last):
...
pandera.errors.SchemaError: <Schema Column: 'year' type=DataType(int64)> failed element-
wise validator 0:
<Check greater_than: greater_than(2000)>
failure cases:
   index failure_case
0 2 1999
```

As you can see in the example above, you can define a schema by sub-classing *SchemaMode1* and defining column/index fields as class attributes. The *check_types()* decorator is required to perform validation of the dataframe at run-time.

Note that Field s apply to both Column and Index objects, exposing the built-in Check s via key-word arguments.

(New in 0.6.2) When you access a class attribute defined on the schema, it will return the name of the column used in the validated pd.DataFrame. In the example above, this will simply be the string "year".

```
print(f"Column name for 'year' is {InputSchema.year}\n")
print(df.loc[:, [InputSchema.year, "day"]])
```

```
Column name for 'year' is year

year day
0 2001 200
1 2002 156
2 2003 365
```

7.2.2 Validate on Initialization

new in 0.8.0

Pandera provides an interface for validating dataframes on initialization. This API uses the pandera.typing.pandas.DataFrame generic type to validated against the SchemaModel type variable on initialization:

```
import pandas as pd
import pandera as pa
from pandera.typing import DataFrame, Series
```

(continues on next page)

7.2. Schema Models 29

```
class Schema(pa.SchemaModel):
    state: Series[str]
    city: Series[str]
    price: Series[int] = pa.Field(in_range={"min_value": 5, "max_value": 20})

df = DataFrame[Schema](
    {
        'state': ['NY','FL','GA','CA'],
        'city': ['New York', 'Miami', 'Atlanta', 'San Francisco'],
        'price': [8, 12, 10, 16],
    }
)
print(df)
```

```
state city price

0 NY New York 8

1 FL Miami 12

2 GA Atlanta 10

3 CA San Francisco 16
```

Refer to Supported DataFrame Libraries to see how this syntax applies to other supported dataframe types.

7.2.3 Converting to DataFrameSchema

You can easily convert a SchemaModel class into a DataFrameSchema:

```
print(InputSchema.to_schema())
```

```
<Schema DataFrameSchema(
    columns={
        'year': <Schema Column(name=year, type=DataType(int64))>
        'month': <Schema Column(name=month, type=DataType(int64))>
        'day': <Schema Column(name=day, type=DataType(int64))>
    },
    checks=[],
    coerce=False,
    dtype=None,
    index=None,
    strict=False
    name=InputSchema,
    ordered=False,
    unique_column_names=False
)>
```

You can also use the *validate()* method to validate dataframes:

```
print(InputSchema.validate(df))
```

```
year month day
0 2001 3 200
```

Or you can use the *SchemaModel()* class directly to validate dataframes, which is syntactic sugar that simply delegates to the *validate()* method.

```
print(InputSchema(df))
```

7.2.4 Excluded attributes

Class variables which begin with an underscore will be automatically excluded from the model. *Config* is also a reserved name. However, *aliases* can be used to circumvent these limitations.

7.2.5 Supported dtypes

Any dtypes supported by pandera can be used as type parameters for Series and Index. There are, however, a couple of gotchas.

7.2.5.1 Dtype aliases

```
import pandera as pa
from pandera.typing import Series, String

class Schema(pa.SchemaModel):
    a: Series[String]
```

7.2.5.2 Type Vs instance

You must give a type, not an instance.

✓ Good:

```
import pandas as pd

class Schema(pa.SchemaModel):
    a: Series[pd.StringDtype]
```

Bad:

```
class Schema(pa.SchemaModel):
    a: Series[pd.StringDtype()]
```

7.2. Schema Models 31

```
Traceback (most recent call last):
...
TypeError: Parameters to generic types must be types. Got string[python].
```

7.2.5.3 Parametrized dtypes

Pandas supports a couple of parametrized dtypes. As of pandas 1.2.0:

Kind of Data	Data Type	Parameters
tz-aware datetime	DatetimeTZDtype	unit, tz
Categorical	CategoricalDtype	categories, ordered
period	PeriodDtype	freq
sparse	SparseDtype	dtype, fill_value
intervals	IntervalDtype	subtype

7.2.5.3.1 Annotated

Parameters can be given via typing. Annotated. It requires python > 3.9 or typing_extensions, which is already a requirement of Pandera. Unfortunately typing. Annotated has not been backported to python 3.6.

✓ Good:

```
try:
    from typing import Annotated # python 3.9+
except ImportError:
    from typing_extensions import Annotated

class Schema(pa.SchemaModel):
    col: Series[Annotated[pd.DatetimeTZDtype, "ns", "est"]]
```

Furthermore, you must pass all parameters in the order defined in the dtype's constructor (see table).

Bad:

```
class Schema(pa.SchemaModel):
    col: Series[Annotated[pd.DatetimeTZDtype, "utc"]]
Schema.to_schema()
```

```
Traceback (most recent call last):
...
TypeError: Annotation 'DatetimeTZDtype' requires all positional arguments ['unit', 'tz'].
```

7.2.5.3.2 Field

✓ Good:

```
class SchemaFieldDatetimeTZDtype(pa.SchemaModel):
    col: Series[pd.DatetimeTZDtype] = pa.Field(dtype_kwargs={"unit": "ns", "tz": "EST"})
```

You cannot use both typing. Annotated and dtype_kwargs.

Bad:

```
class SchemaFieldDatetimeTZDtype(pa.SchemaModel):
    col: Series[Annotated[pd.DatetimeTZDtype, "ns", "est"]] = pa.Field(dtype_kwargs={
        "unit": "ns", "tz": "EST"})
Schema.to_schema()
```

7.2.6 Required Columns

By default all columns specified in the schema are *required*, meaning that if a column is missing in the input DataFrame an exception will be thrown. If you want to make a column optional, annotate it with typing.Optional.

```
from typing import Optional
import pandas as pd
import pandera as pa
from pandera.typing import Series

class Schema(pa.SchemaModel):
    a: Series[str]
    b: Optional[Series[int]]

df = pd.DataFrame({"a": ["2001", "2002", "2003"]})
Schema.validate(df)
```

7.2. Schema Models 33

7.2.7 Schema Inheritance

You can also use inheritance to build schemas on top of a base schema.

```
class BaseSchema(pa.SchemaModel):
   year: Series[str]
class FinalSchema(BaseSchema):
   year: Series[int] = pa.Field(ge=2000, coerce=True) # overwrite the base type
   passengers: Series[int]
    idx: Index[int] = pa.Field(ge=0)
df = pd.DataFrame({
    "year": ["2000", "2001", "2002"],
})
@pa.check_types
def transform(df: DataFrame[BaseSchema]) -> DataFrame[FinalSchema]:
   return (
        df.assign(passengers=[61000, 50000, 45000])
        .set_index(pd.Index([1, 2, 3]))
        .astype({"year": int})
   )
print(transform(df))
```

```
year passengers
1 2000 61000
2 2001 50000
3 2002 45000
```

7.2.8 Config

Schema-wide options can be controlled via the Config class on the SchemaModel subclass. The full set of options can be found in the *BaseConfig* class.

```
class Schema(pa.SchemaModel):
    year: Series[int] = pa.Field(gt=2000, coerce=True)
    month: Series[int] = pa.Field(ge=1, le=12, coerce=True)
    day: Series[int] = pa.Field(ge=0, le=365, coerce=True)

class Config:
    name = "BaseSchema"
    strict = True
    coerce = True
    foo = "bar" # Interpreted as dataframe check
```

It is not required for the Config to subclass BaseConfig but it must be named 'Config'.

See Registered Custom Checks with the Class-based API for details on using registered dataframe checks.

7.2.9 MultiIndex

The MultiIndex capabilities are also supported with the class-based API:

```
import pandera as pa
from pandera.typing import Index, Series

class MultiIndexSchema(pa.SchemaModel):

    year: Index[int] = pa.Field(gt=2000, coerce=True)
    month: Index[int] = pa.Field(ge=1, le=12, coerce=True)
    passengers: Series[int]

class Config:
    # provide multi index options in the config
    multiindex_name = "time"
    multiindex_strict = True
    multiindex_coerce = True

index = MultiIndexSchema.to_schema().index
print(index)
```

```
from pprint import pprint

pprint({name: col.checks for name, col in index.columns.items()})
```

Multiple Index annotations are automatically converted into a MultiIndex. MultiIndex options are given in the Config.

7.2. Schema Models 35

7.2.10 Custom Checks

Unlike the object-based API, custom checks can be specified as class methods.

7.2.10.1 Column/Index checks

```
import pandera as pa
from pandera.typing import Index, Series

class CustomCheckSchema(pa.SchemaModel):

    a: Series[int] = pa.Field(gt=0, coerce=True)
    abc: Series[int]
    idx: Index[str]

    @pa.check("a", name="foobar")
    def custom_check(cls, a: Series[int]) -> Series[bool]:
        return a < 100

    @pa.check("^a", regex=True, name="foobar")
    def custom_check_regex(cls, a: Series[int]) -> Series[bool]:
        return a > 0

    @pa.check("idx")
    def check_idx(cls, idx: Index[int]) -> Series[bool]:
        return idx.str.contains("dog")
```

Note:

- You can supply the key-word arguments of the *Check* class initializer to get the flexibility of *groupby checks*
- Similarly to pydantic, classmethod() decorator is added behind the scenes if omitted.
- You still may need to add the @classmethod decorator after the check() decorator if your static-type checker
 or linter complains.
- Since checks are class methods, the first argument value they receive is a SchemaModel subclass, not an instance of a model.

```
from typing import Dict

class GroupbyCheckSchema(pa.SchemaModel):

    value: Series[int] = pa.Field(gt=0, coerce=True)
    group: Series[str] = pa.Field(isin=["A", "B"])

    @pa.check("value", groupby="group", regex=True, name="check_means")
    def check_groupby(cls, grouped_value: Dict[str, Series[int]]) -> bool:
        return grouped_value["A"].mean() < grouped_value["B"].mean()

df = pd.DataFrame({
    "value": [100, 110, 120, 10, 11, 12],</pre>
```

```
"group": list("AAABBB"),
})
print(GroupbyCheckSchema.validate(df))
```

```
Traceback (most recent call last):
...
pandera.errors.SchemaError: <Schema Column: 'value' type=DataType(int64)> failed series_
-validator 1:
<Check check_means>
```

7.2.10.2 DataFrame Checks

You can also define dataframe-level checks, similar to the *object-based API*, using the dataframe_check() decorator:

```
import pandas as pd
import pandera as pa
from pandera.typing import Index, Series
class DataFrameCheckSchema(pa.SchemaModel):
   col1: Series[int] = pa.Field(gt=0, coerce=True)
   col2: Series[float] = pa.Field(gt=0, coerce=True)
   col3: Series[float] = pa.Field(lt=0, coerce=True)
   @pa.dataframe_check
   def product_is_negative(cls, df: pd.DataFrame) -> Series[bool]:
        return df["col1"] * df["col2"] * df["col3"] < 0</pre>
df = pd.DataFrame({
    "col1": [1, 2, 3],
   "col2": [5, 6, 7],
    "col3": [-1, -2, -3],
})
DataFrameCheckSchema.validate(df)
```

7.2.10.3 Inheritance

The custom checks are inherited and therefore can be overwritten by the subclass.

7.2. Schema Models 37

```
def check_a(cls, a: Series[int]) -> Series[bool]:
    return a < 100

class Child(Parent):
    a: Series[int] = pa.Field(coerce=False)

    @pa.check("a", name="foobar")
    def check_a(cls, a: Series[int]) -> Series[bool]:
        return a > 100

is_a_coerce = Child.to_schema().columns["a"].coerce
print(f"coerce: {is_a_coerce}")
```

```
coerce: False
```

```
df = pd.DataFrame({"a": [1, 2, 3]})
print(Child.validate(df))
```

7.2.11 Aliases

SchemaModel supports columns which are not valid python variable names via the argument alias of Field.

Checks must reference the aliased names.

```
import pandas as pa
import pandas as pd

class Schema(pa.SchemaModel):
    col_2020: pa.typing.Series[int] = pa.Field(alias=2020)
    idx: pa.typing.Index[int] = pa.Field(alias="_idx", check_name=True)

    @pa.check(2020)
    def int_column_lt_100(cls, series):
        return series < 100

df = pd.DataFrame({2020: [99]}, index=[0])</pre>
```

```
df.index.name = "_idx"
print(Schema.validate(df))
```

```
2020
_idx
0 99
```

(New in 0.6.2) The alias is respected when using the class attribute to get the underlying pd.DataFrame column name or index level name.

```
print(Schema.col_2020)
```

```
2020
```

Very similar to the example above, you can also use the variable name directly within the class scope, and it will respect the alias.

Note: To access a variable from the class scope, you need to make it a class attribute, and therefore assign it a default *Field*.

```
import pandera as pa
import pandas as pd

class Schema(pa.SchemaModel):
    a: pa.typing.Series[int] = pa.Field()
    col_2020: pa.typing.Series[int] = pa.Field(alias=2020)

    @pa.check(col_2020)
    def int_column_lt_100(cls, series):
        return series < 100

    @pa.check(a)
    def int_column_gt_100(cls, series):
        return series > 100

df = pd.DataFrame({2020: [99], "a": [101]})
print(Schema.validate(df))
```

```
2020 a
0 99 101
```

7.2. Schema Models 39

7.3 Series Schemas

The SeriesSchema class allows for the validation of pandas Series objects, and are very similar to columns and indexes described in DataFrameSchemas.

```
import pandas as pd
import pandera as pa
# specify multiple validators
schema = pa.SeriesSchema(
    str,
    checks=[
        pa.Check(lambda s: s.str.startswith("foo")),
        pa.Check(lambda s: s.str.endswith("bar")),
       pa.Check(lambda x: len(x) > 3, element_wise=True)
   ],
   nullable=False,
   unique=False,
   name="my_series")
validated_series = schema.validate(
   pd.Series(["foobar", "foobar", "foobar"], name="my_series"))
print(validated_series)
```

```
0 foobar
1 foobar
2 foobar
Name: my_series, dtype: object
```

7.4 Checks

7.4.1 Checking column properties

Check objects accept a function as a required argument, which is expected to take a pa.Series input and output a boolean or a Series of boolean values. For the check to pass, all of the elements in the boolean series must evaluate to True, for example:

```
import pandera as pa
check_lt_10 = pa.Check(lambda s: s <= 10)
schema = pa.DataFrameSchema({"column1": pa.Column(int, check_lt_10)})
schema.validate(pd.DataFrame({"column1": range(10)}))</pre>
```

Multiple checks can be applied to a column:

```
schema = pa.DataFrameSchema({
    "column2": pa.Column(str, [
        pa.Check(lambda s: s.str.startswith("value")),
```

```
pa.Check(lambda s: s.str.split("_", expand=True).shape[1] == 2)
]),
})
```

7.4.2 Built-in Checks

For common validation tasks, built-in checks are available in pandera.

```
import pandera as pa
from pandera import Column, Check, DataFrameSchema

schema = DataFrameSchema({
    "small_values": Column(float, Check.less_than(100)),
    "one_to_three": Column(int, Check.isin([1, 2, 3])),
    "phone_number": Column(str, Check.str_matches(r'^[a-z0-9-]+$')),
})
```

See the *Check* API reference for a complete list of built-in checks.

7.4.3 Vectorized vs. Element-wise Checks

By default, *Check* objects operate on pd.Series objects. If you want to make atomic checks for each element in the Column, then you can provide the element_wise=True keyword argument:

```
import pandas as pd
import pandera as pa
schema = pa.DataFrameSchema({
    "a": pa.Column(
        int,
        checks=[
            # a vectorized check that returns a bool
            pa.Check(lambda s: s.mean() > 5, element_wise=False),
            # a vectorized check that returns a boolean series
            pa.Check(lambda s: s > 0, element_wise=False),
            # an element-wise check that returns a bool
            pa.Check(lambda x: x > 0, element_wise=True),
        ]
   ),
})
df = pd.DataFrame(\{"a": [4, 4, 5, 6, 6, 7, 8, 9]\})
schema.validate(df)
```

element_wise == False by default so that you can take advantage of the speed gains provided by the pd.Series API by writing vectorized checks.

7.4. Checks 41

7.4.4 Handling Null Values

By default, pandera drops null values before passing the objects to validate into the check function. For Series objects null elements are dropped (this also applies to columns), and for DataFrame objects, rows with any null value are dropped.

If you want to check the properties of a pandas data structure while preserving null values, specify Check(..., ignore_na=False) when defining a check.

Note that this is different from the nullable argument in *Column* objects, which simply checks for null values in a column.

7.4.5 Column Check Groups

Column checks support grouping by a different column so that you can make assertions about subsets of the column of interest. This changes the function signature of the *Check* function so that its input is a dict where keys are the group names and values are subsets of the series being validated.

Specifying groupby as a column name, list of column names, or callable changes the expected signature of the *Check* function argument to:

```
Callable[Dict[Any, pd.Series] -> Union[bool, pd.Series]
```

where the dict keys are the discrete keys in the groupby columns.

In the example below we define a *DataFrameSchema* with column checks for height_in_feet using a single column, multiple columns, and a more complex groupby function that creates a new column age_less_than_15 on the fly.

```
import pandas as pd
import pandera as pa
schema = pa.DataFrameSchema({
    "height_in_feet": pa.Column(
        float, [
            # groupby as a single column
            pa.Check(
                lambda g: g[False].mean() > 6,
                groupby="age_less_than_20"),
            # define multiple groupby columns
            pa.Check(
                lambda g: g[(True, "F")].sum() == 9.1,
                groupby=["age_less_than_20", "sex"]),
            # groupby as a callable with signature:
            # (DataFrame) -> DataFrameGroupBy
            pa.Check(
                lambda g: g[(False, "M")].median() == 6.75,
                groupby=lambda df: (
                    df.assign(age_less_than_15=lambda d: d["age"] < 15)</pre>
                    .groupby(["age_less_than_15", "sex"]))),
        ]),
    "age": pa.Column(int, pa.Check(lambda s: s > 0)),
    "age_less_than_20": pa.Column(bool),
    "sex": pa.Column(str, pa.Check(lambda s: s.isin(["M", "F"])))
```

```
df = (
    pd.DataFrame({
        "height_in_feet": [6.5, 7, 6.1, 5.1, 4],
        "age": [25, 30, 21, 18, 13],
        "sex": ["M", "M", "F", "F"]
    })
    .assign(age_less_than_20=lambda x: x["age"] < 20)
)
schema.validate(df)</pre>
```

7.4.6 Wide Checks

pandera is primarily designed to operate on long-form data (commonly known as tidy data), where each row is an observation and each column is an attribute associated with an observation.

However, pandera also supports checks on wide-form data to operate across columns in a DataFrame. For example, if you want to make assertions about height across two groups, the tidy dataset and schema might look like this:

```
import pandas as pd
import pandera as pa

df = pd.DataFrame({
    "height": [5.6, 6.4, 4.0, 7.1],
    "group": ["A", "B", "A", "B"],
})

schema = pa.DataFrameSchema({
    "height": pa.Column(
        float,
        pa.Check(lambda g: g["A"].mean() < g["B"].mean(), groupby="group")
    ),
    "group": pa.Column(str)
})
schema.validate(df)</pre>
```

Whereas the equivalent wide-form schema would look like this:

```
df = pd.DataFrame({
    "height_A": [5.6, 4.0],
    "height_B": [6.4, 7.1],
})
schema = pa.DataFrameSchema(
    columns={
        "height_A": pa.Column(float),
        "height_B": pa.Column(float),
```

(continues on next page)

7.4. Checks 43

```
},
# define checks at the DataFrameSchema-level
checks=pa.Check(
    lambda df: df["height_A"].mean() < df["height_B"].mean()
)
)
schema.validate(df)</pre>
```

You can see that when checks are supplied to the DataFrameSchema checks key-word argument, the check function should expect a pandas DataFrame and should return a bool, a Series of booleans, or a DataFrame of boolean values.

7.4.7 Raise UserWarning on Check Failure

In some cases, you might want to raise a UserWarning and continue execution of your program. The Check and Hypothesis classes and their built-in methods support the keyword argument raise_warning, which is False by default. If set to True, the check will raise a UserWarning instead of raising a SchemaError exception.

Note: Use this feature carefully! If the check is for informational purposes and not critical for data integrity then use raise_warning=True. However, if the assumptions expressed in a Check are necessary conditions to considering your data valid, do not set this option to true.

One scenario where you'd want to do this would be in a data pipeline that does some preprocessing, checks for normality in certain columns, and writes the resulting dataset to a table. In this case, you want to see if your normality assumptions are not fulfilled by certain columns, but you still want the resulting table for further analysis.

```
import warnings
import numpy as np
import pandas as pd
import pandera as pa
from scipy.stats import normaltest
np.random.seed(1000)
df = pd.DataFrame({
    "var1": np.random.normal(loc=0, scale=1, size=1000),
    "var2": np.random.uniform(low=0, high=10, size=1000),
})
normal_check = pa.Hypothesis(
   test=normaltest,
    samples="normal_variable",
    # null hypotheses: sample comes from a normal distribution. The
    # relationship function checks if we cannot reject the null hypothesis,
    # i.e. the p-value is greater or equal to alpha.
   relationship=lambda stat, pvalue, alpha=0.05: pvalue >= alpha,
```

```
error="normality test",
    raise_warning=True,
)

schema = pa.DataFrameSchema(
    columns={
        "var1": pa.Column(checks=normal_check),
        "var2": pa.Column(checks=normal_check),
    }
)

# catch and print warnings
with warnings.catch_warnings(record=True) as caught_warnings:
    warnings.simplefilter("always")
    validated_df = schema(df)
    for warning in caught_warnings:
        print(warning.message)
```

```
<Schema Column(name=var2, type=None)> failed series or dataframe validator 0:
<Check _hypothesis_check: normality test>
```

7.4.8 Registering Custom Checks

pandera now offers an interface to register custom checks functions so that they're available in the *Check* namespace. See *the extensions* document for more information.

7.5 Hypothesis Testing

pandera enables you to perform statistical hypothesis tests on your data.

Note: The hypothesis feature requires a pandera installation with hypotheses dependency set. See the *installation* instructions for more details.

7.5.1 Overview

The *Hypothesis* class defines built in methods, which can be called as in this example of a two-sample t-test:

```
import pandas as pd
import pandera as pa

from pandera import Column, DataFrameSchema, Check, Hypothesis

from scipy import stats

df = (
    pd.DataFrame({
```

```
"height_in_feet": [6.5, 7, 6.1, 5.1, 4],
        "sex": ["M", "M", "F", "F", "F"]
    })
)
schema = DataFrameSchema({
    "height_in_feet": Column(
        float, [
            Hypothesis.two_sample_ttest(
                sample1="M",
                sample2="F"
                groupby="sex",
                relationship="greater_than",
                alpha=0.05,
                equal_var=True),
    ]),
    "sex": Column(str)
})
schema.validate(df)
```

```
Traceback (most recent call last):
...
pandera.SchemaError: <Schema Column: 'height_in_feet' type=float64> failed series_
-validator 0: hypothesis_check: failed two sample ttest between 'M' and 'F'
```

You can also define custom hypotheses by passing in functions to the test and relationship arguments.

The test function takes as input one or multiple array-like objects and should return a stat, which is the test statistic, and pvalue for assessing statistical significance. It also takes key-word arguments supplied by the test_kwargs dict when initializing a Hypothesis object.

The relationship function should take all of the outputs of test as positional arguments, in addition to key-word arguments supplied by the relationship_kwargs dict.

Here's an implementation of the two-sample t-test that uses the scipy implementation:

7.5.2 Wide Hypotheses

pandera is primarily designed to operate on long-form data (commonly known as tidy data), where each row is an observation and columns are attributes associated with the observation.

However, pandera also supports hypothesis testing on wide-form data to operate across columns in a DataFrame.

For example, if you want to make assertions about height across two groups, the tidy dataset and schema might look like this:

```
import pandas as pd
import pandera as pa
from pandera import Check, DataFrameSchema, Column, Hypothesis
df = pd.DataFrame({
    "height": [5.6, 7.5, 4.0, 7.9],
    "group": ["A", "B", "A", "B"],
})
schema = DataFrameSchema({
    "height": Column(
        float, Hypothesis.two_sample_ttest(
            "A", "B",
            groupby="group",
            relationship="less_than",
            alpha=0.05
        )
   ),
    "group": Column(str, Check(lambda s: s.isin(["A", "B"])))
})
schema.validate(df)
```

The equivalent wide-form schema would look like this:

```
import pandas as pd
import pandera as pa
from pandera import DataFrameSchema, Column, Hypothesis
```

```
df = pd.DataFrame({
    "height_A": [5.6, 4.0],
    "height_B": [7.5, 7.9],
})
schema = DataFrameSchema(
    columns={
        "height_A": Column(Float),
        "height_B": Column(Float),
    },
    # define checks at the DataFrameSchema-level
    checks=Hypothesis.two_sample_ttest(
        "height_A", "height_B",
        relationship="less_than",
        alpha=0.05
    )
)
schema.validate(df)
```

7.6 Pandera Data Types

new in 0.7.0

7.6.1 Motivations

Pandera defines its own interface for data types in order to abstract the specifics of dataframe-like data structures in the python ecosystem, such as Apache Spark, Apache Arrow and xarray.

Note: In the following section Pandera Data Type refers to a *pandera.dtypes.DataType* object whereas native data type refers to data types used by third-party libraries that Pandera supports (e.g. pandas).

Most of the time, it is transparent to end users since pandera columns and indexes accept native data types. However, it is possible to extend the pandera interface by:

- modifying the data type check performed during schema validation.
- modifying the behavior of the **coerce** argument for DataFrameSchema.
- adding your **own custom data types**.

7.6.2 DataType basics

All pandera data types inherit from pandera.dtypes.DataType and must be hashable.

A data type implements three key methods:

- pandera.dtypes.DataType.check() which validates that data types are equivalent.
- pandera.dtypes.DataType.coerce() which coerces a data container (e.g. pandas.Series) to the data type.
- The dunder method __str__() which should output the native alias. For example str(pandera.Float64) == "float64"

For pandera's validation methods to be aware of a data type, it has to be registered with the targeted engine via pandera. engines.engine.Engine.register_dtype(). An engine is in charge of mapping a pandera DataType with a native data type counterpart belonging to a third-party library. The mapping can be queried with pandera.engines.engine.Engine.dtype().

As of pandera 0.7.0, only the pandas *Engine* is supported.

7.6.3 Example

Let's extend pandas. BooleanDtype coercion to handle the string literals "True" and "False".

```
import pandas as pd
import pandera as pa
from pandera import dtypes
from pandera.engines import pandas_engine
@pandas_engine.Engine.register_dtype # step 1
@dtypes.immutable # step 2
class LiteralBool(pandas_engine.BOOL): # step 3
    def coerce(self, series: pd.Series) -> pd.Series:
        """Coerce a pandas. Series to date types."""
        if pd.api.types.is_string_dtype(series):
            series = series.replace({"True": 1, "False": 0})
        return series.astype("boolean")
data = pd.Series(["True", "False"], name="literal_bools")
# step 4
print(
   pa.SeriesSchema(LiteralBool(), coerce=True, name="literal_bools")
    .validate(data)
    .dtype
)
```

boolean

The example above performs the following steps:

- 1. Register the data type with the pandas engine.
- 2. pandera.dtypes.immutable() creates an immutable (and hashable) dataclass().

- 3. Inherit *pandera.engines.pandas_engine.BOOL*, which is the pandera representation of pandas. BooleanDtype. This is not mandatory but it makes our life easier by having already implemented all the required methods.
- 4. Check that our new data type can coerce the string literals.

So far we did not override the default behavior:

```
import pandera as pa
pa.SeriesSchema("boolean", coerce=True).validate(data)
```

```
Traceback (most recent call last):
...
pandera.errors.SchemaError: Error while coercing 'literal_bools' to type boolean: Need.

to pass bool-like values
```

To completely replace the default *BOOL*, we need to supply all the equivalent representations to *register_dtype()*. Behind the scenes, when pa.SeriesSchema("boolean") is called the corresponding pandera data type is looked up using *pandera.engines.engine.Engine.dtype()*.

```
print(f"before: {pandas_engine.Engine.dtype('boolean').__class__}")

@pandas_engine.Engine.register_dtype(
        equivalents=["boolean", pd.BooleanDtype, pd.BooleanDtype()],
)
@dtypes.immutable
class LiteralBool(pandas_engine.BOOL):
    def coerce(self, series: pd.Series) -> pd.Series:
        """Coerce a pandas.Series to date types."""
        if pd.api.types.is_string_dtype(series):
            series = series.replace({"True": 1, "False": 0})
        return series.astype("boolean")

print(f"after: {pandas_engine.Engine.dtype('boolean').__class__}")

for dtype in ["boolean", pd.BooleanDtype, pd.BooleanDtype()]:
        pa.SeriesSchema(dtype, coerce=True).validate(data)
```

```
before: <class 'pandera.engines.pandas_engine.BOOL'>
after: <class 'LiteralBool'>
```

Note: For convenience, we specified both pd.BooleanDtype and pd.BooleanDtype() as equivalents. That gives us more flexibility in what pandera schemas can recognize (see last for-loop above).

7.6.4 Parametrized data types

Some data types can be parametrized. One common example is pandas. Categorical Dtype.

The equivalents argument of <code>register_dtype()</code> does not handle this situation but will automatically register a <code>classmethod()</code> with signature <code>from_parametrized_dtype(cls, equivalent:...)</code> if the decorated <code>DataType</code> defines it. The <code>equivalent</code> argument must be type-annotated because it is leveraged to dispatch the input of <code>dtype</code> to the appropriate <code>from_parametrized_dtype</code> class method.

For example, here is a snippet from pandera.engines.pandas_engine.Category:

```
import pandas as pd
from pandera import dtypes

@classmethod
def from_parametrized_dtype(
    cls, cat: Union[dtypes.Category, pd.CategoricalDtype]
):
    """Convert a categorical to
    a Pandera :class:`pandera.dtypes.pandas_engine.Category`."""
    return cls(categories=cat.categories, ordered=cat.ordered) # type: ignore
```

Note: The dispatch mechanism relies on functools.singledispatch(). Unlike the built-in implementation, typing.Union is recognized.

7.6.5 Defining the coerce_value method

For pandera datatypes to understand how to correctly report coercion errors, it needs to know how to coerce an individual value into the specified type.

All pandas data types are supported: numpy -based datatypes use the underlying numpy dtype to coerce an individual value. The pandas -native datatypes like CategoricalDtype and BooleanDtype are also supported.

As an example of a special-cased coerce_value implementation, see coerce_value():

```
`{literalinclude} ../../pandera/engines/pandas_engine.py --- lines: 446-452 --- `And coerce_value():
`{literalinclude} ../../pandera/engines/pandas_engine.py --- lines: 208-214 --- `
```

7.7 Decorators for Pipeline Integration

If you have an existing data pipeline that uses pandas data structures, you can use the *check_input()* and *check_output()* decorators to easily check function arguments or returned variables from existing functions.

7.7.1 Check Input

Validates input pandas DataFrame/Series before entering the wrapped function.

```
import pandas as pd
import pandera as pa
from pandera import DataFrameSchema, Column, Check, check_input
df = pd.DataFrame({
  "column1": [1, 4, 0, 10, 9],
   "column2": [-1.3, -1.4, -2.9, -10.1, -20.4],
})
in_schema = DataFrameSchema({
   "column1": Column(int,
                     Check(lambda x: 0 \le x \le 10, element_wise=True)),
   "column2": Column(float, Check(lambda x: x < -1.2)),
})
# by default, check_input assumes that the first argument is
# dataframe/series.
@check_input(in_schema)
def preprocessor(dataframe):
   dataframe["column3"] = dataframe["column1"] + dataframe["column2"]
   return dataframe
preprocessed_df = preprocessor(df)
print(preprocessed_df)
```

```
column1 column2 column3
                        -0.3
0
         1
               -1.3
                         2.6
         4
               -1.4
1
2
         0
               -2.9
                        -2.9
3
        10
              -10.1
                        -0.1
4
              -20.4
                        -11.4
```

You can also provide the argument name as a string

```
@check_input(in_schema, "dataframe")
def preprocessor(dataframe):
    ...
```

Or an integer representing the index in the positional arguments.

```
@check_input(in_schema, 1)
def preprocessor(foo, dataframe):
    ...
```

7.7.2 Check Output

The same as check_input, but this decorator checks the output DataFrame/Series of the decorated function.

```
import pandas as pd
import pandera as pa
from pandera import DataFrameSchema, Column, Check, check_output
preprocessed_df = pd.DataFrame({
   "column1": [1, 4, 0, 10, 9],
})
# assert that all elements in "column1" are zero
out_schema = DataFrameSchema({
    "column1": Column(int, Check(lambda x: x == 0))
})
# by default assumes that the pandas DataFrame/Schema is the only output
@check_output(out_schema)
def zero_column_1(df):
   df["column1"] = 0
   return df
# you can also specify in the index of the argument if the output is list-like
@check_output(out_schema, 1)
def zero_column_1_arg(df):
   df["column1"] = 0
   return "foobar", df
# or the key containing the data structure to verify if the output is dict-like
@check_output(out_schema, "out_df")
def zero_column_1_dict(df):
   df["column1"] = 0
   return {"out_df": df, "out_str": "foobar"}
# for more complex outputs, you can specify a function
@check_output(out_schema, lambda x: x[1]["out_df"])
def zero_column_1_custom(df):
   df["column1"] = 0
   return ("foobar", {"out_df": df})
zero_column_1(preprocessed_df)
zero_column_1_arg(preprocessed_df)
zero_column_1_dict(preprocessed_df)
zero_column_1_custom(preprocessed_df)
```

7.7.3 Check IO

For convenience, you can also use the *check_io()* decorator where you can specify input and output schemas more concisely:

```
import pandas as pd
import pandera as pa
from pandera import DataFrameSchema, Column, Check, check_input
df = pd.DataFrame({
  "column1": [1, 4, 0, 10, 9],
   "column2": [-1.3, -1.4, -2.9, -10.1, -20.4],
})
in_schema = DataFrameSchema({
   "column1": Column(int),
   "column2": Column(float),
})
out_schema = in_schema.add_columns({"column3": Column(float)})
@pa.check_io(df1=in_schema, df2=in_schema, out=out_schema)
def preprocessor(df1, df2):
   return (df1 + df2).assign(column3=lambda x: x.column1 + x.column2)
preprocessed_df = preprocessor(df, df)
print(preprocessed_df)
```

```
column1 column2 column3
        2
               -2.6
                        -0.6
0
         8
               -2.8
                          5.2
1
2
                        -5.8
         0
               -5.8
3
        20
              -20.2
                        -0.2
4
              -40.8
                        -22.8
        18
```

7.7.4 Decorate Functions and Coroutines

All pandera decorators work on synchronous as well as asynchronous code, on both bound and unbound functions/coroutines. For example, one can use the same decorators on:

- sync/async functions
- · sync/async methods
- sync/async class methods
- · sync/async static methods

All decorators work on sync/async regular/class/static methods of metaclasses as well.

```
import pandera as pa
from pandera.typing import DataFrame, Series
```

```
class Schema(pa.SchemaModel):
   col1: Series[int]
   class Config:
        strict = True
@pa.check_types
async def coroutine(df: DataFrame[Schema]) -> DataFrame[Schema]:
   return df
@pa.check_types
async def function(df: DataFrame[Schema]) -> DataFrame[Schema]:
   return df
class SomeClass:
   @pa.check_output(Schema.to_schema())
   async def regular_coroutine(self, df) -> DataFrame[Schema]:
        return df
   @classmethod
   @pa.check_input(Schema.to_schema(), "df")
   async def class_coroutine(cls, df):
        return Schema.validate(df)
   @staticmethod
   @pa.check_io(df=Schema.to_schema(), out=Schema.to_schema())
   def static_method(df):
        return df
```

7.8 Schema Inference

New in version 0.4.0

With simple use cases, writing a schema definition manually is pretty straight-forward with pandera. However, it can get tedious to do this with dataframes that have many columns of various data types.

To help you handle these cases, the *infer_schema()* function enables you to quickly infer a draft schema from a pandas dataframe or series. Below is a simple example:

```
import pandas as pd
import pandera as pa

from pandera import Check, Column, DataFrameSchema

df = pd.DataFrame({
    "column1": [5, 10, 20],
    "column2": ["a", "b", "c"],
    "column3": pd.to_datetime(["2010", "2011", "2012"]),
})
```

```
schema = pa.infer_schema(df)
print(schema)
```

```
<Schema DataFrameSchema(
    columns={
        'column1': <Schema Column(name=column1, type=DataType(int64))>
        'column2': <Schema Column(name=column2, type=DataType(object))>
        'column3': <Schema Column(name=column3, type=DataType(datetime64[ns]))>
},
    checks=[],
    coerce=True,
    dtype=None,
    index=<Schema Index(name=None, type=DataType(int64))>,
    strict=False
    name=None,
    ordered=False,
    unique_column_names=False
)>
```

These inferred schemas are **rough drafts** that shouldn't be used for validation without modification. You can modify the inferred schema to obtain the schema definition that you're satisfied with.

For DataFrameSchema objects, the following methods create modified copies of the schema:

- add_columns()
- remove_columns()
- update_column()

For SeriesSchema objects:

set_checks()

The section below describes two workflows for persisting and modifying an inferred schema.

7.8.1 Schema Persistence

The schema persistence feature requires a pandera installation with the io extension. See the *installation* instructions for more details.

There are two ways of persisting schemas, inferred or otherwise.

7.8.1.1 Write to a Python script

You can also write your schema to a python script with to_script():

```
# supply a file-like object, Path, or str to write to a file. If not
# specified, to_script will output the code as a string.
schema_script = schema.to_script()
print(schema_script)
```

57

```
from pandas import Timestamp
from pandera import DataFrameSchema, Column, Check, Index, MultiIndex
schema = DataFrameSchema(
    columns={
        "column1": Column(
            dtype=pandera.engines.numpy_engine.Int64,
            checks=[
                Check.greater_than_or_equal_to(min_value=5.0),
                Check.less_than_or_equal_to(max_value=20.0),
            ],
            nullable=False.
            unique=False,
            coerce=False,
            required=True,
            regex=False,
        ),
        "column2": Column(
            dtype=pandera.engines.numpy_engine.Object,
            checks=None,
            nullable=False,
            unique=False,
            coerce=False,
            required=True,
            regex=False,
        ),
        "column3": Column(
            dtype=pandera.engines.pandas_engine.DateTime,
            checks=[
                Check.greater_than_or_equal_to(
                    min_value=Timestamp("2010-01-01 00:00:00")
                Check.less_than_or_equal_to(
                    max_value=Timestamp("2012-01-01 00:00:00")
                ),
            ],
            nullable=False,
            unique=False,
            coerce=False,
            required=True,
            regex=False,
        ),
    },
    index=Index(
        dtype=pandera.engines.numpy_engine.Int64,
        checks=[
            Check.greater_than_or_equal_to(min_value=0.0),
            Check.less_than_or_equal_to(max_value=2.0),
        nullable=False,
        coerce=False,
        name=None,
                                                                            (continues on next page)
```

7.8. Schema Inference

```
coerce=True,
  strict=False,
  name=None,
)
```

As a python script, you can iterate on an inferred schema and use it to validate data once you are satisfied with your schema definition.

7.8.1.2 Write to YAML

You can also write the schema object to a yaml file with to_yaml(), and you can then read it into memory with from_yaml(). The to_yaml() and from_yaml() is a convenience method for this functionality.

```
# supply a file-like object, Path, or str to write to a file. If not
# specified, to_yaml will output a yaml string.
yaml_schema = schema.to_yaml()
print(yaml_schema.replace(f"{pa.__version__}", "{PANDERA_VERSION}"))
```

```
schema_type: dataframe
version: {PANDERA_VERSION}
columns:
  column1:
    dtype: int64
    nullable: false
    checks:
      greater_than_or_equal_to: 5.0
      less_than_or_equal_to: 20.0
    unique: false
    coerce: false
    required: true
    regex: false
  column2:
    dtype: object
    nullable: false
    checks: null
    unique: false
    coerce: false
    required: true
    regex: false
  column3:
    dtype: datetime64[ns]
    nullable: false
      greater_than_or_equal_to: '2010-01-01 00:00:00'
      less_than_or_equal_to: '2012-01-01 00:00:00'
    unique: false
    coerce: false
    required: true
    regex: false
checks: null
index:
```

```
- dtype: int64
nullable: false
checks:
    greater_than_or_equal_to: 0.0
    less_than_or_equal_to: 2.0
    name: null
    unique: false
    coerce: false
coerce: true
strict: false
unique: null
```

You can edit this yaml file by specifying column names under the column key. The respective values map onto key-word arguments in the *Column* class.

Note: Currently, only built-in *Check* methods are supported under the checks key.

7.9 Lazy Validation

New in version 0.4.0

By default, when you call the validate method on schema or schema component objects, a *SchemaError* is raised as soon as one of the assumptions specified in the schema is falsified. For example, for a *DataFrameSchema* object, the following situations will raise an exception:

- a column specified in the schema is not present in the dataframe.
- if strict=True, a column in the dataframe is not specified in the schema.
- the data type does not match.
- if coerce=True, the dataframe column cannot be coerced into the specified data type.
- the *Check* specified in one of the columns returns False or a boolean series containing at least one False value.

For example:

```
import pandas as pd
import pandera as pa

from pandera import Check, Column, DataFrameSchema

df = pd.DataFrame({"column": ["a", "b", "c"]})

schema = pa.DataFrameSchema({"column": Column(int)})
schema.validate(df)
```

```
Traceback (most recent call last):
...
SchemaError: expected series 'column' to have type int64, got object
```

For more complex cases, it is useful to see all of the errors raised during the validate call so that you can debug the causes of errors on different columns and checks. The lazy keyword argument in the validate method of all schemas and schema components gives you the option of doing just this:

```
import pandas as pd
import pandera as pa
from pandera import Check, Column, DataFrameSchema
schema = pa.DataFrameSchema(
   columns={
        "int_column": Column(int),
        "float_column": Column(float, Check.greater_than(0)),
        "str_column": Column(str, Check.equal_to("a")),
        "date_column": Column(pa.DateTime),
   },
   strict=True
)
df = pd.DataFrame({
   "int_column": ["a", "b", "c"],
   "float_column": [0, 1, 2],
    "str_column": ["a", "b", "d"],
    "unknown_column": None,
})
schema.validate(df, lazy=True)
```

```
Traceback (most recent call last):
pandera.errors.SchemaErrors: A total of 5 schema errors were found.
Error Counts
_____
- column not in schema: 1

                            check
schema_context column
                            column_in_dataframe
                                                        [date_column]
DataFrameSchema <NA>
                                                                                    1
                            column_in_schema
                                                     [unknown_column]
                                                                                    1
               float_column dtype('float64')
Column
                                                              [int64]
                                                                                    1
                            dtype('int64')
               int_column
                                                             [object]
                                                                                    1
               str_column
                            equal_to(a)
                                                               [b, d]
                                                                                    2
Usage Tip
Directly inspect all errors by catching the exception:
```

```
try:
    schema.validate(dataframe, lazy=True)
except SchemaErrors as err:
    err.failure_cases # dataframe of schema errors
    err.data # invalid dataframe
```

As you can see from the output above, a *SchemaErrors* exception is raised with a summary of the error counts and failure cases caught by the schema. You can also see from the **Usage Tip** that you can catch these errors and inspect the failure cases in a more granular form:

```
try:
    schema.validate(df, lazy=True)
except pa.errors.SchemaErrors as err:
    print("Schema errors and failure cases:")
    print(err.failure_cases)
    print("\nDataFrame object that failed validation:")
    print(err.data)
```

```
Schema errors and failure cases:
                           column
                                                  check check_number
    schema_context
  DataFrameSchema
                             None
                                       column_in_schema
                                                                 None
                                   column_in_dataframe
   DataFrameSchema
                             None
                                                                 None
2
            Column
                                         dtype('int64')
                       int_column
                                                                 None
3
            Column float_column
                                       dtype('float64')
                                                                 None
4
            Column
                    float_column
                                        greater_than(0)
                                                                     0

                       1
                 d
                       2
6
DataFrame object that failed validation:
              float_column str_column unknown_column
  int_column
0
                          0
                                                  None
                                      a
1
           b
                          1
                                      b
                                                  None
                          2
                                      d
2
           c
                                                  None
```

7.10 Data Synthesis Strategies

new in 0.6.0

pandera provides a utility for generating synthetic data purely from pandera schema or schema component objects. Under the hood, the schema metadata is collected to create a data-generating strategy using hypothesis, which is a property-based testing library.

7.10.1 Basic Usage

Once you've defined a schema, it's easy to generate examples:

```
column1 column2 column3
0 10 0.25 foo
1 10 0.25 foo
2 10 0.25 foo
```

Note that here we've constrained the specific values in each column using *Check* s in order to make the data generation process deterministic for documentation purposes.

7.10.2 Usage in Unit Tests

The example method is available for all schemas and schema components, and is primarily meant to be used interactively. It *could* be used in a script to generate test cases, but hypothesis recommends against doing this and instead using the strategy method to create a hypothesis strategy that can be used in pytest unit tests.

```
import hypothesis

def processing_fn(df):
    return df.assign(column4=df.column1 * df.column2)

@hypothesis.given(schema.strategy(size=5))
def test_processing_fn(dataframe):
    result = processing_fn(dataframe)
    assert "column4" in result
```

The above example is trivial, but you get the idea! Schema objects can create a strategy that can then be collected by a pytest runner. We could also run the tests explicitly ourselves, or run it as a unittest. TestCase. For more information on testing with hypothesis, see the hypothesis quick start guide.

A more practical example involves using *schema transformations*. We can modify the function above to make sure that processing_fn actually outputs the correct result:

```
out_schema = schema.add_columns({"column4": pa.Column(float)})

@pa.check_output(out_schema)
def processing_fn(df):
    return df.assign(column4=df.column1 * df.column2)

@hypothesis.given(schema.strategy(size=5))
def test_processing_fn(dataframe):
    processing_fn(dataframe)
```

Now the test_processing_fn simply becomes an execution test, raising a *SchemaError* if processing_fn doesn't add column4 to the dataframe.

7.10.3 Strategies and Examples from Schema Models

You can also use the *class-based API* to generate examples. Here's the equivalent schema model for the above examples:

```
from pandera.typing import Series, DataFrame

class InSchema(pa.SchemaModel):
    column1: Series[int] = pa.Field(eq=10)
    column2: Series[float] = pa.Field(eq=0.25)
    column3: Series[str] = pa.Field(eq="foo")

class OutSchema(InSchema):
    column4: Series[float]

@pa.check_types
def processing_fn(df: DataFrame[InSchema]) -> DataFrame[OutSchema]:
    return df.assign(column4=df.column1 * df.column2)

@hypothesis.given(InSchema.strategy(size=5))
def test_processing_fn(dataframe):
    processing_fn(dataframe)
```

7.10.4 Checks as Constraints

As you may have noticed in the first example, *Check* s further constrain the data synthesized from a strategy. Without checks, the example method would simply generate any value of the specified type. You can specify multiple checks on a column and pandera should be able to generate valid data under those constraints.

```
schema_multiple_checks = pa.DataFrameSchema({
    "column1": pa.Column(
        float, checks=[
            pa.Check.gt(0),
            pa.Check.lt(1e10),
            pa.Check.notin([-100, -10, 0]),
        ]
    )
})
```

```
for _ in range(5):
    # generate 10 rows of the dataframe
    sample_data = schema_multiple_checks.example(size=3)

# validate the sampled data
    schema_multiple_checks(sample_data)
```

One caveat here is that it's up to you to define a set of checks that are jointly satisfiable. If not, an Unsatisfiable exception will be raised:

```
Traceback (most recent call last):
...
Unsatisfiable: Unable to satisfy assumptions of hypothesis example_generating_inner_
__function.
```

7.10.4.1 Check Strategy Chaining

If you specify multiple checks for a particular column, this is what happens under the hood:

- The first check in the list is the *base strategy*, which hypothesis uses to generate data.
- All subsequent checks filter the values generated by the previous strategy such that it fulfills the constraints of current check.

To optimize efficiency of the data-generation procedure, make sure to specify the most restrictive constraint of a column as the *base strategy* and build other constraints on top of it.

7.10.4.2 In-line Custom Checks

One of the strengths of pandera is its flexibility with regard to defining custom checks on the fly:

```
schema_inline_check = pa.DataFrameSchema({
    "col": pa.Column(str, pa.Check(lambda s: s.isin({"foo", "bar"})))
})
```

One of the disadvantages of this is that the fallback strategy is to simply apply the check to the generated data, which can be highly inefficient. In this case, hypothesis will generate strings and try to find examples of strings that are in the set {"foo", "bar"}, which will be very slow and most likely raise an Unsatisfiable exception. To get around this limitation, you can register custom checks and define strategies that correspond to them.

7.10.5 Defining Custom Strategies

All built-in *Check* s are associated with a data synthesis strategy. You can define your own data synthesis strategies by using the *extensions API* to register a custom check function with a corresponding strategy.

7.11 Extensions

new in 0.6.0

7.11.1 Registering Custom Check Methods

One of the strengths of pandera is its flexibility in enabling you to defining in-line custom checks on the fly:

```
import pandera as pa

# checks elements in a column/dataframe
element_wise_check = pa.Check(lambda x: x < 0, element_wise=True)

# applies the check function to a dataframe/series
vectorized_check = pa.Check(lambda series_or_df: series_or_df < 0)</pre>
```

However, there are two main disadvantages of schemas with inline custom checks:

- 1. they are not serializable with the IO interface.
- 2. you can't use them to *synthesize data* because the checks are not associated with a hypothesis strategy.

pandera now offers a way to register custom checks so that they're available in the *Check* class as a check method. Here let's define a custom method that checks whether a pandas object contains elements that lie within two values.

```
import pandera as pa
import pandera.extensions as extensions
import pandas as pd

@extensions.register_check_method(statistics=["min_value", "max_value"])
def is_between(pandas_obj, *, min_value, max_value):
    return (min_value <= pandas_obj) & (pandas_obj <= max_value)

schema = pa.DataFrameSchema({
    "col": pa.Column(int, pa.Check.is_between(min_value=1, max_value=10))
})

data = pd.DataFrame({"col": [1, 5, 10]})
print(schema(data))</pre>
```

```
col
0 1
1 5
2 10
```

As you can see, a custom check's first argument is a pandas series or dataframe by default (more on that later), followed by keyword-only arguments, specified with the * syntax.

7.11. Extensions 65

The <code>register_check_method()</code> requires you to explicitly name the check statistics via the keyword argument, which are essentially the constraints placed by the check on the pandas data structure.

7.11.2 Specifying a Check Strategy

To specify a check strategy with your custom check, you'll need to install the *strategies extension*. First let's look at a trivially simple example, where the check verifies whether a column is equal to a certain value:

```
def custom_equals(pandas_obj, *, value):
    return pandas_obj == value
```

The corresponding strategy for this check would be:

```
from typing import Optional
import hypothesis
import pandera.strategies as st

def equals_strategy(
    pandera_dtype: pa.DataType,
    strategy: Optional[st.SearchStrategy] = None,
    *,
    value,
):
    if strategy is None:
        return st.pandas_dtype_strategy(
            pandera_dtype, strategy=hypothesis.strategies.just(value),
        )
        return strategy.filter(lambda x: x == value)
```

As you may notice, the pandera strategy interface is has two arguments followed by keyword-only arguments that match the check function keyword-only check statistics. The pandera_dtype positional argument is useful for ensuring the correct data type. In the above example, we're using the pandas_dtype_strategy() strategy to make sure the generated value is of the correct data type.

The optional strategy argument allows us to use the check strategy as a *base strategy* or a *chained strategy*. There's a detail that we're responsible for implementing in the strategy function body: we need to handle two cases to account for *strategy chaining*:

- 1. when the strategy function is being used as a base strategy, i.e. when strategy is None
- 2. when the strategy function is being chained from a previously-defined strategy, i.e. when strategy is not None.

Finally, to register the custom check with the strategy, use the register_check_method() decorator:

```
@extensions.register_check_method(
    statistics=["value"], strategy=equals_strategy
)
def custom_equals(pandas_obj, *, value):
    return pandas_obj == value
```

Let's unpack what's going in here. The custom_equals function only has a single statistic, which is the value argument, which we've also specified in $register_check_method()$. This means that the associated check strategy must match its keyword-only arguments.

Going back to our is_between function example, here's what the strategy would look like:

```
def in_between_strategy(
    pandera_dtype: pa.DataType,
    strategy: Optional[st.SearchStrategy] = None,
    min_value,
    max_value
):
    if strategy is None:
        return st.pandas_dtype_strategy(
            pandera_dtype,
            min_value=min_value,
            max_value=max_value,
            exclude_min=False,
            exclude_max=False,
        )
    return strategy.filter(lambda x: min_value <= x <= max_value)</pre>
@extensions.register_check_method(
    statistics=["min_value", "max_value"],
    strategy=in_between_strategy,
def is_between_with_strat(pandas_obj, *, min_value, max_value):
    return (min_value <= pandas_obj) & (pandas_obj <= max_value)</pre>
```

7.11.3 Check Types

The extensions module also supports registering *element-wise* and *groupby* checks.

7.11.3.1 Element-wise Checks

```
@extensions.register_check_method(
    statistics=["val"],
    check_type="element_wise",
)
def element_wise_equal_check(element, *, val):
    return element == val
```

Note that the first argument of element_wise_equal_check is a single element in the column or dataframe.

7.11.3.2 Groupby Checks

In this groupby check, we're verifying that the values of one column for group_a are, on average, greater than those of group_b:

```
from typing import Dict

@extensions.register_check_method(
    statistics=["group_a", "group_b"],
    check_type="groupby",
)
```

(continues on next page)

7.11. Extensions 67

```
def groupby_check(dict_groups: Dict[str, pd.Series], *, group_a, group_b):
    return dict_groups[group_a].mean() > dict_groups[group_b].mean()

data = pd.DataFrame({
        "values": [20, 10, 1, 15],
        "groups": list("xxyy"),
})

schema = pa.DataFrameSchema({
        "values": pa.Column(
        int,
        pa.Check.groupby_check(group_a="x", group_b="y", groupby="groups"),
      ),
      "groups": pa.Column(str),
})

print(schema(data))
```

```
      values groups

      0
      20
      x

      1
      10
      x

      2
      1
      y

      3
      15
      y
```

7.11.4 Registered Custom Checks with the Class-based API

Since registered checks are part of the Check namespace, you can also use custom checks with the class-based API:

```
from pandera.typing import Series

class Schema(pa.SchemaModel):
    col1: Series[str] = pa.Field(custom_equals="value")
    col2: Series[int] = pa.Field(is_between={"min_value": 0, "max_value": 10})

data = pd.DataFrame({
    "col1": ["value"] * 5,
    "col2": range(5)
})

print(Schema.validate(data))
```

```
col1 col2
0 value 0
1 value 1
2 value 2
3 value 3
4 value 4
```

DataFrame checks can be attached by using the *Config* class. Any field names that do not conflict with existing fields of *BaseConfig* and do not start with an underscore (_) are interpreted as the name of registered checks. If the value is a tuple or dict, it is interpreted as the positional or keyword arguments of the check, and as the first argument otherwise.

For example, to register zero, one, and two statistic dataframe checks one could do the following:

```
import pandera as pa
import pandera.extensions as extensions
import numpy as np
import pandas as pd
@extensions.register_check_method()
def is_small(df):
   return sum(df.shape) < 1000
@extensions.register_check_method(statistics=["fraction"])
def total_missing_fraction_less_than(df, *, fraction: float):
   return (1 - df.count().sum().item() / sum(df.shape)) < fraction</pre>
@extensions.register_check_method(statistics=["col_a", "colb"])
def col_mean_a_greater_than_b(df, *, col_a: str, col_b: str):
   return df[col_a].mean() > df[col_b].mean()
from pandera.typing import Series
class Schema(pa.SchemaModel):
   col1: Series[float] = pa.Field(nullable=True, ignore_na=False)
   col2: Series[float] = pa.Field(nullable=True, ignore_na=False)
   class Config:
        is\_small = ()
        total_missing_fraction_less_than = 0.6
        col_mean_a_greater_than_b = {"col_a": "col2", "col_b": "col1"}
data = pd.DataFrame({
    "col1": [float('nan')] * 3 + [0.5, 0.3, 0.1],
   "col2": np.arange(6.),
})
print(Schema.validate(data))
```

```
col1 col2
  NaN
         0.0
0
1
   NaN
         1.0
2
  NaN
        2.0
3
   0.5
        3.0
4
   0.3 4.0
   0.1
         5.0
```

7.11. Extensions 69

7.12 Data Format Conversion

new in 0.9.0

The class-based API provides configuration options for converting data to/from supported serialization formats in the context of <code>check_types()</code> -decorated functions.

Note: Currently, pandera.typing.pandas.DataFrame is the only data type that supports this feature.

Consider this simple example:

```
import pandera as pa
from pandera.typing import DataFrame, Series

class InSchema(pa.SchemaModel):
    str_col: Series[str] = pa.Field(unique=True, isin=[*"abcd"])
    int_col: Series[int]

class OutSchema(InSchema):
    float_col: pa.typing.Series[float]

@pa.check_types
def transform(df: DataFrame[InSchema]) -> DataFrame[OutSchema]:
    return df.assign(float_col=1.1)
```

With the schema type annotations and *check_types()* decorator, the transform function validates DataFrame inputs and outputs according to the InSchema and OutSchema definitions.

But what if your input data is serialized in parquet format, and you want to read it into memory, validate the DataFrame, and then pass it to a downstream function for further analysis? Similarly, what if you want the output of transform to be a list of dictionary records instead of a pandas DataFrame?

7.12.1 The to/from_format Configuration Options

To easily fulfill the use cases described above, you can implement the read/write logic by hand, or you can configure schemas to do so. We can first define a subclass of InSchema with additional configuration so that our transform function can read data directly from parquet files or buffers:

```
class InSchemaParquet(InSchema):
    class Config:
        from_format = "parquet"
```

Then, we define subclass of OutSchema to specify that transform should output a list of dictionaries representing the rows of the output dataframe.

```
class OutSchemaDict(OutSchema):
    class Config:
        to_format = "dict"
        to_format_kwargs = {"orient": "records"}
```

Note that the {to/from}_format_kwargs configuration option should be supplied with a dictionary of key-word arguments to be passed into the respective pandas to_{format} method.

Finally, we redefine our transform function:

```
@pa.check_types
def transform(df: DataFrame[InSchemaParquet]) -> DataFrame[OutSchemaDict]:
    return df.assign(float_col=1.1)
```

We can test this out using a buffer to store the parquet file.

Note: A string or path-like object representing the filepath to a parquet file would also be a valid input to transform.

```
import io
import json

buffer = io.BytesIO()
data = pd.DataFrame({"str_col": [*"abc"], "int_col": range(3)})
data.to_parquet(buffer)
buffer.seek(0)

dict_output = transform(buffer)
print(json.dumps(dict_output, indent=4))
```

```
{
        "str_col": "a",
        "int_col": 0,
        "float_col": 1.1
   },
    {
        "str_col": "b",
        "int_col": 1,
        "float_col": 1.1
   },
        "str_col": "c",
        "int_col": 2,
        "float_col": 1.1
   }
]
```

7.12.2 Takeaway

Data Format Conversion using the {to/from}_format configuration option can modify the behavior of *check_types()* -decorated functions to convert input data from a particular serialization format into a dataframe. Additionally, you can convert the output data from a dataframe to potentially another format.

This dovetails well with the FastAPI Integration for validating the inputs and outputs of app endpoints.

7.13 Supported DataFrame Libraries

Pandera started out as a pandas-specific dataframe validation library, and moving forward its core functionality will continue to support pandas. However, pandera's adoption has resulted in the realization that it can be a much more powerful tool by supporting other dataframe-like formats.

7.13.1 Domain-specific Data Validation

The pandas ecosystem provides support for domain-specific data manipulation, and by extension pandera can provide access to data types, methods, and data container types specific to these libraries.

GeoPandas An extension of pandas that adds geospatial data processing capabilities.

7.13.1.1 Data Validation with GeoPandas

new in 0.9.0

GeoPandas is an extension of Pandas that adds support for geospatial data. You can use pandera to validate GeoDataFrame() and GeoSeries() objects directly. First, install pandera with the geopandas extra:

```
pip install pandera[geopandas]
```

Then you can use pandera schemas to validate geodataframes. In the example below we'll use the *class-based API* to define a SchemaModel for validation.

```
import geopandas as gpd
import pandas as pd
import pandera as pa
from shapely.geometry import Polygon

geo_schema = pa.DataFrameSchema({
    "geometry": pa.Column("geometry"),
    "region": pa.Column(str),
})

geo_df = gpd.GeoDataFrame({
    "geometry": [
        Polygon(((0, 0), (0, 1), (1, 1), (1, 0))),
        Polygon(((0, 0), (0, -1), (-1, -1), (-1, 0))))
    ],
    "region": ["NA", "SA"]
})
```

```
print(geo_schema.validate(geo_df))
```

```
geometry region

O POLYGON ((0.00000 0.00000, 0.00000 1.00000, 1.... NA

1 POLYGON ((0.00000 0.00000, 0.00000 -1.00000, -... SA
```

You can also use the GeometryDtype data type in either instantiated or un-instantiated form:

```
geo_schema = pa.DataFrameSchema({
    "geometry": pa.Column(gpd.array.GeometryDtype),
    # or
    "geometry": pa.Column(gpd.array.GeometryDtype()),
})
```

If you want to validate-on-instantiation, you can use the GeoDataFrame generic type with the schema model defined above:

```
geometry region

0 POLYGON ((0.00000 0.00000, 0.00000 1.00000, 1... NA
1 POLYGON ((0.00000 0.00000, 0.00000 -1.00000, -... SA
```

7.13.2 Scaling Up Data Validation

Pandera provides multiple ways of scaling up data validation to dataframes that don't fit into memory. Fortunately, pandera doesn't have to re-invent the wheel. Standing on shoulders of giants, it integrates with the existing ecosystem of libraries that allow you to perform validations on out-of-memory dataframes.

Dask	Apply pandera schemas to Dask dataframe partitions.	
Fugue	Apply pandera schemas to distributed dataframe partitions with Fugue.	
Koalas [Deprecated] A pandas drop-in replacement, distributed using a Spark backend.		
Pyspark Exposes a pyspark.pandas module, distributed using a Spark backend.		
Modin	A pandas drop-in replacement, distributed using a Ray or Dask backend.	

7.13.2.1 Data Validation with Dask

new in 0.8.0

Dask is a distributed compute framework that offers a pandas-like dataframe API. You can use pandera to validate DataFrame() and Series() objects directly. First, install pandera with the dask extra:

```
pip install pandera[dask]
```

Then you can use pandera schemas to validate dask dataframes. In the example below we'll use the *class-based API* to define a SchemaModel for validation.

```
import dask.dataframe as dd
import pandas as pd
import pandera as pa
from pandera.typing.dask import DataFrame, Series
class Schema(pa.SchemaModel):
    state: Series[str]
    city: Series[str]
    price: Series[int] = pa.Field(in_range={"min_value": 5, "max_value": 20})
ddf = dd.from_pandas(
    pd.DataFrame(
            'state': ['FL','FL','FL','CA','CA','CA'],
            'city': [
                'Orlando',
                'Miami',
                'Tampa',
                'San Francisco',
                'Los Angeles',
                'San Diego',
            ],
            'price': [8, 12, 10, 16, 20, 18],
        }
    ),
    npartitions=2
```

```
pandera_ddf = Schema(ddf)
print(pandera_ddf)
```

```
Dask DataFrame Structure:

state city price
npartitions=2

object object int64

... ...

...

bask Name: validate, 4 tasks
```

As you can see, passing the dask dataframe into Schema will produce another dask dataframe which hasn't been evaluated yet. What this means is that pandera will only validate when the dask graph is evaluated.

```
print(pandera_ddf.compute())
```

```
state
                   city price
0
     FL
                Orlando
                              8
     FL
1
                  Miami
                             12
2
     FL
                  Tampa
                             10
3
     CA
        San Francisco
                             16
4
     CA
           Los Angeles
                             20
5
     CA
              San Diego
                             18
```

You can also use the check_types() decorator to validate dask dataframes at runtime:

```
@pa.check_types
def function(ddf: DataFrame[Schema]) -> DataFrame[Schema]:
    return ddf[ddf["state"] == "CA"]
print(function(ddf).compute())
```

```
state city price
3 CA San Francisco 16
4 CA Los Angeles 20
5 CA San Diego 18
```

And of course, you can use the object-based API to validate dask dataframes:

```
schema = pa.DataFrameSchema({
    "state": pa.Column(str),
    "city": pa.Column(str),
    "price": pa.Column(int, pa.Check.in_range(min_value=5, max_value=20))
})
print(schema(ddf).compute())
```

```
state city price

0 FL Orlando 8

1 FL Miami 12
```

```
2
     FL
                  Tampa
                             10
3
     CA
         San Francisco
                             16
4
     CA
            Los Angeles
                             20
5
              San Diego
     CA
                             18
```

7.13.2.2 Data Validation with Fugue

Validation on big data comes in two forms. The first is performing one set of validations on data that doesn't fit in memory. The second happens when a large dataset is comprised of multiple groups that require different validations. In pandas semantics, this would be the equivalent of a groupby-validate operation. This section will cover using pandera for both of these scenarios.

Pandera only supports pandas DataFrames at the moment. However, the same pandera code can be used on top of Spark or Dask engines with Fugue. These computation engines allow validation to be performed in a distributed setting. Fugue is an open source abstraction layer that ports Python, pandas, and SQL code to Spark and Dask.

7.13.2.2.1 What is Fugue?

Fugue serves as an interface to distributed computing. Because of its non-invasive design, existing Python code can be scaled to a distributed setting without significant changes.

To run the example, Fugue needs to installed separately. Using pip:

```
pip install fugue[spark]
```

This will also install PySpark because of the spark extra. Dask is available with the dask extra.

7.13.2.2.2 Example

In this example, a pandas DataFrame is created with state, city and price columns. Pandera will be used to validate that the price column values are within a certain range.

```
state
                    city
                          price
0
     FL
                Orlando
                               8
1
     FL
                  Miami
                              12
2
     FL
                  Tampa
                              10
3
     CA
        San Francisco
                              16
```

```
4 CA Los Angeles 20
5 CA San Diego 18
```

Validation is then applied using pandera. A price_validation function is created that runs the validation. None of this will be new.

The transform function in Fugue is the easiest way to use Fugue with existing Python functions as seen in the following code snippet. The first two arguments are the DataFrame and function to apply. The keyword argument schema is required because schema is strictly enforced in distributed settings. Here, the schema is simply * because no new columns are added.

The last part of the transform function is the engine. Here, the SparkExecutionEngine is used to run the code on top of Spark. Fugue also has a DaskExecutionEngine, and passing nothing uses the default pandas-based ExecutionEngine. Because the SparkExecutionEngine is used, the result becomes a Spark DataFrame.

```
from fugue import transform
from fugue_spark import SparkExecutionEngine

spark_df = transform(data, price_validation, schema="*", engine=SparkExecutionEngine)
spark_df.show()
```

```
+----+
            city|price|
Istatel
  FLI
          Orlando|
                   81
  FL|
           Miami|
                  12|
           Tampal
                  101
  CA|San Francisco|
                  16|
  CA| Los Angeles|
                  201
        San Diego
+----+
```

7.13.2.2.3 Validation by Partition

There is an interesting use case that arises with bigger datasets. Frequently, there are logical groupings of data that require different validations. In the earlier sample data, the price range for the records with state FL is lower than the range for the state CA. Two <code>DataFrameSchema</code> will be created to reflect this. Notice their ranges for the <code>Check</code> differ.

```
price_check_FL = DataFrameSchema({
    "price": Column(int, Check.in_range(min_value=7,max_value=13)),
})
```

```
price_check_CA = DataFrameSchema({
    "price": Column(int, Check.in_range(min_value=15,max_value=21)),
})
price_checks = {'CA': price_check_CA, 'FL': price_check_FL}
```

A slight modification is needed to our price_validation function. Fugue will partition the whole dataset into multiple pandas DataFrames. Think of this as a groupby. By the time price_validation is used, it only contains the data for one state. The appropriate DataFrameSchema is pulled and then applied.

To partition our data by state, all we need to do is pass it into the transform function through the partition argument. This splits up the data across different workers before they each run the price_validation function. Again, this is like a groupby-validation.

_	DataFrame :str city:str	price:long
CA	San Francisco	16
CA	Los Angeles	20
CA	San Diego	18
FL	Orlando	8
FL	Miami	12
FL	Tampa	10
Total	count: 6	

Note: Because operations in a distributed setting are applied per partition, statistical validators will be applied on each partition rather than the global dataset. If no partitioning scheme is specified, Spark and Dask use default partitions. Be careful about using operations like mean, min, and max without partitioning beforehand.

All row-wise validations scale well with this set-up.

7.13.2.3 Data Validation with Koalas

Note: Koalas has been deprecated since version 0.10.0. Please refer to the *pyspark page* for validating pyspark dataframes.

7.13.2.4 Data Validation with Pyspark (New)

new in 0.10.0

Pyspark is a distributed compute framework that offers a pandas drop-in replacement dataframe implementation via the pyspark.pandas API. You can use pandera to validate DataFrame() and Series() objects directly. First, install pandera with the dask extra:

```
pip install pandera[pyspark]
```

Then you can use pandera schemas to validate pyspark dataframes. In the example below we'll use the *class-based API* to define a SchemaModel for validation.

```
import pyspark.pandas as ps
import pandas as pd
import pandera as pa
from pandera.typing.pyspark import DataFrame, Series
class Schema(pa.SchemaModel):
    state: Series[str]
   city: Series[str]
   price: Series[int] = pa.Field(in_range={"min_value": 5, "max_value": 20})
# create a pyspark.pandas dataframe that's validated on object initialization
df = DataFrame[Schema](
   {
        'state': ['FL','FL','FL','CA','CA','CA'],
        'city': [
            'Orlando'.
            'Miami',
            'Tampa',
            'San Francisco',
            'Los Angeles',
            'San Diego',
        ],
        'price': [8, 12, 10, 16, 20, 18],
   }
print(df)
```

```
state city price

0 FL Orlando 8

1 FL Miami 12
```

```
2
     FL
                  Tampa
                             10
3
     CA
        San Francisco
                              16
4
     CA
            Los Angeles
                             20
5
              San Diego
     CA
                             18
```

You can also use the check_types() decorator to validate pyspark pandas dataframes at runtime:

```
@pa.check_types
def function(df: DataFrame[Schema]) -> DataFrame[Schema]:
    return df[df["state"] == "CA"]
print(function(df))
```

```
state city price
3 CA San Francisco 16
4 CA Los Angeles 20
5 CA San Diego 18
```

And of course, you can use the object-based API to validate dask dataframes:

```
schema = pa.DataFrameSchema({
    "state": pa.Column(str),
    "city": pa.Column(str),
    "price": pa.Column(int, pa.Check.in_range(min_value=5, max_value=20))
})
print(schema(df))
```

```
state
                   city price
0
     FL
                Orlando
                              8
     FL
1
                  Miami
                             12
2
     FL
                  Tampa
                             10
3
     CA
         San Francisco
                             16
4
     CA
            Los Angeles
                             20
5
     CA
              San Diego
                             18
```

7.13.2.5 Data Validation with Modin

new in 0.8.0

Modin is a distributed compute framework that offers a pandas drop-in replacement dataframe implementation. You can use pandera to validate DataFrame() and Series() objects directly. First, install pandera with the dask extra:

```
pip install pandera[modin]  # installs both ray and dask backends
pip install pandera[modin-ray]  # only ray backend
pip install pandera[modin-dask]  # only dask backend
```

Then you can use pandera schemas to validate modin dataframes. In the example below we'll use the *class-based API* to define a SchemaModel for validation.

```
import modin.pandas as pd
import pandas as pd
```

```
import pandera as pa
from pandera.typing.modin import DataFrame, Series
class Schema(pa.SchemaModel):
   state: Series[str]
   city: Series[str]
   price: Series[int] = pa.Field(in_range={"min_value": 5, "max_value": 20})
# create a modin dataframe that's validated on object initialization
df = DataFrame[Schema](
   {
        'state': ['FL','FL','FL','CA','CA','CA'],
        'city': [
            'Orlando',
            'Miami',
            'Tampa',
            'San Francisco',
            'Los Angeles',
            'San Diego',
        'price': [8, 12, 10, 16, 20, 18],
    }
print(df)
```

```
state
                  city price
     FL
               Orlando
1
     FL
                 Miami
                            12
2
     FL
                 Tampa
                            10
3
     CA San Francisco
                            16
4
     CA
           Los Angeles
                            20
5
     CA
             San Diego
                            18
```

You can also use the check_types() decorator to validate modin dataframes at runtime:

```
@pa.check_types
def function(df: DataFrame[Schema]) -> DataFrame[Schema]:
    return df[df["state"] == "CA"]
print(function(df))
```

```
state city price
3 CA San Francisco 16
4 CA Los Angeles 20
5 CA San Diego 18
```

And of course, you can use the object-based API to validate dask dataframes:

```
schema = pa.DataFrameSchema({
    "state": pa.Column(str),
    "city": pa.Column(str),
    "price": pa.Column(int, pa.Check.in_range(min_value=5, max_value=20))
})
print(schema(df))
```

```
state
                   city price
0
     FL
                Orlando
1
     FL
                  Miami
                             12
     FL
                  Tampa
2
                             10
3
     CA San Francisco
                             16
4
     CA
           Los Angeles
                             20
5
             San Diego
                             18
     CA
```

Note: Don't see a library that you want supported? Check out the github issues to see if that library is in the roadmap. If it isn't, open up a new issue to add support for it!

7.14 Integrations

Pandera ships with integrations with other tools in the Python ecosystem, with the goal of interoperating with libraries that you know and love.

FastAPI	Use pandera SchemaModels in your FastAPI app
Frictionless	Convert frictionless schemas to pandera schemas
Hypothesis	Use the hypothesis library to generate valid data under your schema's constraints.
Муру	Type-lint your pandas and pandera code with mypy for static type safety [experimental
Pydantic	Use pandera SchemaModels when defining your pydantic BaseModels

7.14.1 FastAPI

new in 0.9.0

Since both FastAPI and Pandera integrates seamlessly with Pydantic, you can use the *SchemaMode1* types to validate incoming or outgoing data with respect to your API endpoints.

7.14.1.1 Using SchemaModels to Validate Endpoint Inputs and Outputs

Suppose we want to process transactions, where each transaction has an id and cost. We can model this with a pandera schema model:

```
# pylint: skip-file
from typing import Optional
from pydantic import BaseModel, Field
```

```
import pandera as pa

class Transactions(pa.SchemaModel):
    id: pa.typing.Series[int]
    cost: pa.typing.Series[float] = pa.Field(ge=0, le=1000)

class Config:
    coerce = True
```

Also suppose that we expect our endpoint to add a name to the transaction data:

```
class TransactionsOut(Transactions):
   id: pa.typing.Series[int]
   cost: pa.typing.Series[float]
   name: pa.typing.Series[str]
```

Let's also assume that the output of the endpoint should be a list of dictionary records containing the named transactions data. We can do this easily with the to_format option in the schema model <code>BaseConfig</code>.

```
class TransactionsDictOut(TransactionsOut):
    class Config:
        to_format = "dict"
        to_format_kwargs = {"orient": "records"}
```

Note that the to_format_kwargs is a dictionary of key-word arguments to be passed into the respective pandas to_{format} method.

Next we'll create a FastAPI app and define a /transactions/ POST endpoint:

```
from fastapi import FastAPI, File
from pandera.typing import DataFrame

app = FastAPI()

@app.post("/transactions/", response_model=DataFrame[TransactionsDictOut])
def create_transactions(transactions: DataFrame[Transactions]):
    output = transactions.assign(name="foo")
        ... # do other stuff, e.g. update backend database with transactions
    return output
```

7.14.1.2 Reading File Uploads

Similar to the TransactionsDictOut example to convert dataframes to a particular format as an endpoint response, pandera also provides a from_format schema model configuration option to read a dataframe from a particular serialization format.

```
class TransactionsParquet(Transactions):
    class Config:
        from_format = "parquet"
```

Let's also define a response model for the /file/ upload endpoint:

7.14. Integrations 83

```
class TransactionsJsonOut(TransactionsOut):
    class Config:
        to_format = "json"
        to_format_kwargs = {"orient": "records"}

class ResponseModel(BaseModel):
    filename: str
    df: pa.typing.DataFrame[TransactionsJsonOut]
```

In the next example, we use the pandera *UploadFile* type to upload a parquet file to the /file/ POST endpoint and return a response containing the filename and the modified data in json format.

```
from pandera.typing.fastapi import UploadFile

@app.post("/file/", response_model=ResponseModel)
def create_upload_file(
    file: UploadFile[DataFrame[TransactionsParquet]] = File(...),
):
    return {
        "filename": file.filename,
        "df": file.data.assign(name="foo"),
    }
```

Pandera's *UploadFile* type is a subclass of FastAPI's UploadFile but it exposes a .data property containing the pandera-validated dataframe.

7.14.1.3 Takeaway

With the FastAPI and Pandera integration, you can use Pandera *SchemaMode1* types to validate the dataframe inputs and outputs of your FastAPI endpoints.

7.14.2 Reading Third-Party Schema

new in 0.7.0

Pandera now accepts schema from other data validation frameworks. This requires a pandera installation with the io extension; please see the *installation* instructions for more details.

7.14.2.1 Frictionless Data Schema

Note: Please see the Frictionless schema documentation for more information on this standard.

```
pandera.io.from_frictionless_schema(schema)
```

Create a *DataFrameSchema* from either a frictionless json/yaml schema file saved on disk, or from a frictionless schema already loaded into memory.

Each field from the frictionless schema will be converted to a pandera column specification using *FrictionlessFieldParser* to map field characteristics to pandera column specifications.

Parameters schema (Union[str, Path, Dict, Schema]) – the frictionless schema object (or a string/Path to the location on disk of a schema specification) to parse.

Return type DataFrameSchema

Returns dataframe schema with frictionless field specs converted to pandera column checks and constraints for use as normal.

Example

Here, we're defining a very basic frictionless schema in memory before parsing it and then querying the resulting *DataFrameSchema* object as per any other Pandera schema:

```
>>> from pandera.io import from_frictionless_schema
>>>
>>> FRICTIONLESS_SCHEMA = {
        "fields": [
. . .
            {
                "name": "column_1",
                "type": "integer",
                "constraints": {"minimum": 10, "maximum": 99}
            },
                "name": "column_2",
                "type" "string",
                "constraints": {"maxLength": 10, "pattern": "\S+"}
            }.
        ],
        "primaryKey": "column_1"
. . .
   }
>>> schema = from_frictionless_schema(FRICTIONLESS_SCHEMA)
>>> schema.columns["column_1"].checks
[<Check in_range: in_range(10, 99)>]
>>> schema.columns["column_1"].required
True
>>> schema.columns["column_1"].unique
>>> schema.columns["column_2"].checks
[<Check str_length: str_length(None, 10)>, <Check str_matches: str_matches(re.
→compile('^\\S+$'))>]
```

under the hood, this uses the FrictionlessFieldParser class to parse each frictionless field (column):

class pandera.io.FrictionlessFieldParser(field, primary_keys)

Parses frictionless data schema field specifications so we can convert them to an equivalent Pandera Column schema.

For this implementation, we are using field names, constraints and types but leaving other frictionless parameters out (e.g. foreign keys, type formats, titles, descriptions).

Parameters

- **field** a field object from a frictionless schema.
- **primary_keys** the primary keys from a frictionless schema. These are used to ensure primary key fields are treated properly no duplicates, no missing values etc.

property checks: Optional[Dict]

Convert a set of frictionless schema field constraints into checks.

This parses the standard set of frictionless constraints which can be found here and maps them into the equivalent pandera checks.

7.14. Integrations 85

Return type Optional[Dict]

Returns a dictionary of pandera *Check* objects which capture the standard constraint logic of a frictionless schema field.

property coerce: bool

Determine whether values within this field should be coerced.

This currently returns True for all fields within a frictionless schema.

Return type bool

property dtype: str

Determine what type of field this is, so we can feed that into *DataType*. If no type is specified in the frictionless schema, we default to string values.

```
Return type str
```

Returns the pandas-compatible representation of this field type as a string.

property nullable: bool

Determine whether this field can contain missing values.

If a field is a primary key, this will return False.

Return type bool

property regex: bool

Determine whether this field name should be used for regex matches.

This currently returns False for all fields within a frictionless schema.

Return type bool

property required: bool

Determine whether this field must exist within the data.

This currently returns True for all fields within a frictionless schema.

Return type bool

to_pandera_column()

Export this field to a column spec dictionary.

Return type Dict

property unique: bool

Determine whether this field can contain duplicate values.

If a field is a primary key, this will return True.

Return type bool

7.14.3 Mypy

new in 0.8.0

Pandera integrates with mypy to provide static type-linting of dataframes, relying on pandas-stubs for typing information.

```
pip install pandera[mypy]
```

Then enable the plugin in your mypy.ini or setug.cfg file:

```
[mypy]
plugins = pandera.mypy
```

Note: Mypy static type-linting is supported for only pandas dataframes.

Warning: This functionality is experimental. Since the pandas-stubs type stub annotations don't always match the official pandas effort to support type annotations), installing the `pandera[mypy] extra may yield false positives in your pandas code, many of which are are documented in tests/mypy/modules.

We encourage beta users to file an issue if they find any false positives or negatives being reported by mypy. A list of such issues can be found here.

In the example below, we define a few schemas to see how type-linting with pandera works.

```
import pandas as pd
import pandera as pa
from pandera.typing import DataFrame, Series

class Schema(pa.SchemaModel):
    id: Series[int]
    name: Series[str]

class SchemaOut(pa.SchemaModel):
    age: Series[int]

class AnotherSchema(pa.SchemaModel):
    id: Series[int]
    first_name: Series[str]
```

The mypy linter will complain if the output type of the function body doesn't match the function's return signature.

```
def fn(df: DataFrame[Schema]) -> DataFrame[SchemaOut]:
   return df.assign(age=30).pipe(DataFrame[SchemaOut]) # mypy okay
```

(continues on next page)

7.14. Integrations 87

```
def fn_pipe_incorrect_type(df: DataFrame[Schema]) -> DataFrame[SchemaOut]:
    return df.assign(age=30).pipe(DataFrame[AnotherSchema]) # mypy error
    # error: Argument 1 to "pipe" of "NDFrame" has incompatible type
    "Type[DataFrame[Any]]"; # noqa
    # expected "Union[Callable[..., DataFrame[SchemaOut]], Tuple[Callable[...,
    DataFrame[SchemaOut]], str]]" [arg-type] # noqa

def fn_assign_copy(df: DataFrame[Schema]) -> DataFrame[SchemaOut]:
    return df.assign(age=30) # mypy error
    # error: Incompatible return value type (got "pandas.core.frame.DataFrame",
    # expected "pandera.typing.pandas.DataFrame[SchemaOut]") [return-value]
```

It'll also complain if the input type doesn't match the expected input type. Note that we're using the pandera.typing. pandas.DataFrame generic type to define dataframes that are validated against the <code>SchemaModel</code> type variable on initialization.

```
schema_df = DataFrame[Schema]({"id": [1], "name": ["foo"]})
pandas_df = pd.DataFrame({"id": [1], "name": ["foo"]})
another_df = DataFrame[AnotherSchema]({"id": [1], "first_name": ["foo"]})

fn(schema_df) # mypy okay

fn(pandas_df) # mypy error
# error: Argument 1 to "fn" has incompatible type "pandas.core.frame.DataFrame"; # noqa
# expected "pandera.typing.pandas.DataFrame[Schema]" [arg-type]

fn(another_df) # mypy error
# error: Argument 1 to "fn" has incompatible type "DataFrame[AnotherSchema]";
# expected "DataFrame[Schema]" [arg-type]
```

To make mypy happy with respect to the return type, you can either initialize a dataframe of the expected type:

```
def fn_pipe_dataframe(df: DataFrame[Schema]) -> DataFrame[SchemaOut]:
    return df.assign(age=30).pipe(DataFrame[SchemaOut]) # mypy okay
```

Note: If you use the approach above with the check_types() decorator, pandera will do its best to not to validate the dataframe twice if it's already been initialized with the DataFrame[Schema](**data) syntax.

Or use typing.cast() to indicate to mypy that the return value of the function is of the correct type.

```
def fn_cast_dataframe(df: DataFrame[Schema]) -> DataFrame[SchemaOut]:
    return cast(DataFrame[SchemaOut], df.assign(age=30)) # mypy okay
```

7.14.3.1 Limitations

An important caveat to static type-linting with pandera dataframe types is that, since pandas dataframes are mutable objects, there's no way for mypy to know whether a mutated instance of a *SchemaMode1*-typed dataframe has the correct contents. Fortunately, we can simply rely on the check_types() decorator to verify that the output dataframe is valid.

Consider the examples below:

```
def fn_pipe_dataframe(df: DataFrame[Schema]) -> DataFrame[SchemaOut]:
    return df.assign(age=30).pipe(DataFrame[SchemaOut]) # mypy okay

def fn_cast_dataframe(df: DataFrame[Schema]) -> DataFrame[SchemaOut]:
    return cast(DataFrame[SchemaOut], df.assign(age=30)) # mypy okay

@pa.check_types
def fn_mutate_inplace(df: DataFrame[Schema]) -> DataFrame[SchemaOut]:
    out = df.assign(age=30).pipe(DataFrame[SchemaOut])
    out.drop(["age"], axis=1, inplace=True)
    return out # okay for mypy, pandera raises error

@pa.check_types
def fn_assign_and_get_index(df: DataFrame[Schema]) -> DataFrame[SchemaOut]:
    return df.assign(foo=30).iloc[:3] # okay for mypy, pandera raises error
```

Even though the outputs of these functions are incorrect, mypy doesn't catch the error during static type-linting but pandera will raise a *SchemaError* or *SchemaErrors* exception at runtime, depending on whether you're doing *lazy validation* or not.

```
@pa.check_types
def fn_cast_dataframe_invalid(df: DataFrame[Schema]) -> DataFrame[SchemaOut]:
    return cast(
        DataFrame[SchemaOut], df
    ) # okay for mypy, pandera raises error
```

7.14.4 Pydantic

new in 0.8.0

7.14.4.1 Using Pandera Schemas in Pydantic Models

SchemaModel is fully compatible with pydantic. You can specify a SchemaModel in a pydantic BaseModel as you would any other field:

```
import pandas as pd
import pandera as pa
from pandera.typing import DataFrame, Series
import pydantic
```

(continues on next page)

7.14. Integrations 89

```
class SimpleSchema(pa.SchemaModel):
    str_col: Series[str] = pa.Field(unique=True)

class PydanticModel(pydantic.BaseModel):
    x: int
    df: DataFrame[SimpleSchema]

valid_df = pd.DataFrame({"str_col": ["hello", "world"]})
PydanticModel(x=1, df=valid_df)

invalid_df = pd.DataFrame({"str_col": ["hello", "hello"]})
PydanticModel(x=1, df=invalid_df)
```

```
Traceback (most recent call last):
...
ValidationError: 1 validation error for PydanticModel
df
series 'str_col' contains duplicate values:
1 hello
Name: str_col, dtype: object (type=value_error)
```

Other pandera components are also compatible with pydantic:

Note: The SeriesSchema, DataFrameSchema and schema_components types validates the type of a schema object, e.g. if your pydantic BaseModel contained a schema object, not a pandas object.

- SchemaModel
- DataFrameSchema
- SeriesSchema
- MultiIndex
- Column
- Index

7.14.4.2 Using Pydantic Models in Pandera Schemas

new in 0.10.0

You can also use a pydantic BaseModel in a pandera schema. Suppose you had a Record model:

```
from pydantic import BaseModel
import pandera as pa

class Record(BaseModel):
    name: str
```

```
xcoord: str
ycoord: int
```

The PydanticModel datatype enables you to specify the Record model as a row-wise type.

```
import pandas as pd
from pandera.engines.pandas_engine import PydanticModel

class PydanticSchema(pa.SchemaModel):
    """Pandera schema using the pydantic model."""

class Config:
    """Config with dataframe-level data type."""

dtype = PydanticModel(Record)
    coerce = True # this is required, otherwise a SchemaInitError is raised
```

Note: By combining dtype=PydanticModel(...) and coerce=True, pandera will apply the pydantic model validation process to each row of the dataframe, converting the model back to a dictionary with the *BaseModel.dict()* method.

The equivalent pandera schema would look like this:

```
class PanderaSchema(pa.SchemaModel):
    """Pandera schema that's equivalent to PydanticSchema."""

name: pa.typing.Series[str]
    xcoord: pa.typing.Series[int]
    ycoord: pa.typing.Series[int]
```

Note: Since the PydanticModel datatype applies the BaseModel constructor to each row of the dataframe, using PydanticModel might not scale well with larger datasets.

If you want to help benchmark, consider contributing a benchmark script

Note: Don't see a library that you want supported? Check out the github issues to see if that library is in the roadmap. If it isn't, open up a new issue to add support for it!

7.14. Integrations 91

7.15 API

Core	The core objects for defining pandera schemas	
Data Types	Data types for type checking and coercion.	
Schema Models	Alternative class-based API for defining pandera schemas.	
Decorators	Decorators for integrating pandera schemas with python functions.	
Schema Inference	Bootstrap schemas from real data	
IO Utilities	Utility functions for reading/writing schemas	
Data Synthesis Strategies	Module of functions for generating data from schemas.	
Extensions	Utility functions for extending pandera functionality	
Errors	Pandera-specific exceptions	

7.15.1 Core

7.15.1.1 Schemas

pandera.schemas.DataFrameSchema	A light-weight pandas DataFrame validator.
pandera.schemas.SeriesSchema	Series validator.

7.15.1.1.1 pandera.schemas.DataFrameSchema

A light-weight pandas DataFrame validator.

Initialize DataFrameSchema validator.

Parameters

- columns (mapping of column names and column schema component.) a dict where keys are column names and values are Column objects specifying the datatypes and properties of a particular column.
- **checks** (*CheckList*) dataframe-wide checks.
- **index** specify the datatypes and properties of the index.
- **dtype** (*PandasDtypeInputTypes*) datatype of the dataframe. This overrides the data types specified in any of the columns. If a string is specified, then assumes one of the valid pandas string values: http://pandas.pydata.org/pandas-docs/stable/basics.html#dtypes.
- **coerce** (*bool*) whether or not to coerce all of the columns on validation. This has no effect on columns where dtype=None
- **strict** (*Union* [bool, str]) ensure that all and only the columns defined in the schema are present in the dataframe. If set to 'filter', only the columns in the schema will be passed to the validated dataframe. If set to filter and columns defined in the schema are not present in the dataframe, will throw an error.
- name (Optional[str]) name of the schema.
- **ordered** (*bool*) whether or not to validate the columns order.

- **unique** (*Optional* [*Union* [*str*, *List*[*str*]]]) a list of columns that should be jointly unique.
- unique_column_names (bool) whether or not column names must be unique.
- title (Optional[str]) A human-readable label for the schema.
- **description** (*Optional* [*str*]) An arbitrary textual description of the schema.

Raises *SchemaInitError* – if impossible to build schema from parameters

Examples

Use the pandas API to define checks, which takes a function with the signature: pd.Series -> Union[bool, pd.Series] where the output series contains boolean values.

See here for more usage details.

Attributes

coerce	Whether to coerce series to specified type.
description	An arbitrary textual description of the schema.
dtype	Get the dtype property.
dtypes	A dict where the keys are column names and values
	are DataType s for the column.
ordered	Whether or not to validate the columns order.
title	A human-readable label for the schema.
unique	List of columns that should be jointly unique.
unique_column_names	Whether multiple columns with the same name can
	be present.

7.15. API 93

Methods

init	Initialize DataFrameSchema validator.
add_columns	Create a copy of the DataFrameSchema with extra
	columns.
coerce_dtype	Coerce dataframe to the type specified in dtype.
example	Generate an example of a particular size.
from_yaml	Create DataFrameSchema from yaml file.
get_dtypes	Same as the dtype property, but expands columns
	where regex == True based on the supplied
	dataframe.
remove_columns	Removes columns from a DataFrameSchema and re-
	turns a new copy.
rename_columns	Rename columns using a dictionary of key-value
	pairs.
reset_index	A method for resetting the Index of a
	DataFrameSchema
select_columns	Select subset of columns in the schema.
set_index	A method for setting the Index of a
	DataFrameSchema, via an existing Column or
	list of columns.
strategy	Create a hypothesis strategy for generating a
	DataFrame.
to_script	Create DataFrameSchema from yaml file.
to_yaml	Write DataFrameSchema to yaml file.
update_column	Create copy of a DataFrameSchema with updated
	column properties.
update_columns	Create copy of a DataFrameSchema with updated
	column properties.
validate	Check if all columns in a dataframe have a column in
	the Schema.
call	Alias for DataFrameSchema.validate() method.

7.15.1.1.1 pandera.schemas.DataFrameSchema.__init__

DataFrameSchema.__init__(columns=None, checks=None, index=None, dtype=None, coerce=False, strict=False, name=None, ordered=False, unique=None, unique_column_names=False, title=None, description=None)

Initialize DataFrameSchema validator.

Parameters

- **columns** (mapping of column names and column schema component.) a dict where keys are column names and values are Column objects specifying the datatypes and properties of a particular column.
- **checks** (*CheckList*) dataframe-wide checks.
- **index** specify the datatypes and properties of the index.
- **dtype** (*PandasDtypeInputTypes*) datatype of the dataframe. This overrides the data types specified in any of the columns. If a string is specified, then assumes one of the valid pandas string values: http://pandas.pydata.org/pandas-docs/stable/basics.html#dtypes.

- **coerce** (*bool*) whether or not to coerce all of the columns on validation. This has no effect on columns where dtype=None
- **strict** (*Union[bool, str]*) ensure that all and only the columns defined in the schema are present in the dataframe. If set to 'filter', only the columns in the schema will be passed to the validated dataframe. If set to filter and columns defined in the schema are not present in the dataframe, will throw an error.
- name (Optional[str]) name of the schema.
- ordered (bool) whether or not to validate the columns order.
- unique (Optional[Union[str, List[str]]]) a list of columns that should be jointly unique.
- unique_column_names (bool) whether or not column names must be unique.
- title (Optional [str]) A human-readable label for the schema.
- **description** (*Optional[str]*) An arbitrary textual description of the schema.

Raises *SchemaInitError* – if impossible to build schema from parameters

Examples

Use the pandas API to define checks, which takes a function with the signature: pd.Series -> Union[bool, pd.Series] where the output series contains boolean values.

```
schema_withchecks = pa.DataFrameSchema({
        "probability": pa.Column(
             float, pa.Check(lambda s: (s \ge 0) \& (s \le 1))),
. . .
        # check that the "category" column contains a few discrete
. . .
        # values, and the majority of the entries are dogs.
        "category": pa.Column(
. . .
             str, [
. . .
                 pa.Check(lambda s: s.isin(["dog", "cat", "duck"])),
. . .
                 pa.Check(lambda s: (s == "dog").mean() > 0.5),
. . .
             ]),
. . .
... })
```

See *here* for more usage details.

7.15.1.1.1.2 pandera.schemas.DataFrameSchema.add columns

DataFrameSchema.add_columns(extra_schema_cols)

Create a copy of the DataFrameSchema with extra columns.

Parameters extra_schema_cols (DataFrameSchema) - Additional columns of the format

Return type ForwardRef

Returns a new *DataFrameSchema* with the extra_schema_cols added.

Example

To add columns to the schema, pass a dictionary with column name and Column instance key-value pairs.

```
>>> import pandera as pa
>>>
>>> example_schema = pa.DataFrameSchema(
           "category": pa.Column(str),
. . .
           "probability": pa.Column(float),
       }
. . .
...)
>>> print(
        example_schema.add_columns({"even_number": pa.Column(pa.Bool)})
...)
<Schema DataFrameSchema(
    columns={
        'category': <Schema Column(name=category, type=DataType(str))>
        'probability': <Schema Column(name=probability, type=DataType(float64))>
        'even_number': <Schema Column(name=even_number, type=DataType(bool))>
    },
    checks=[],
    coerce=False,
    dtype=None,
    index=None,
    strict=False
   name=None,
    ordered=False,
    unique_column_names=False
)>
```

See also:

remove_columns()

7.15.1.1.1.3 pandera.schemas.DataFrameSchema.coerce_dtype

DataFrameSchema.coerce_dtype(obj)

Coerce dataframe to the type specified in dtype.

Parameters obj (DataFrame) – dataframe to coerce.

Return type DataFrame

Returns dataframe with coerced dtypes

7.15.1.1.1.4 pandera.schemas.DataFrameSchema.example

```
DataFrameSchema.example(size=None, n_regex_columns=1)
```

Generate an example of a particular size.

Parameters size (Optional[int]) – number of elements in the generated DataFrame.

Return type DataFrame

Returns pandas DataFrame object.

7.15.1.1.1.5 pandera.schemas.DataFrameSchema.from_yaml

```
classmethod DataFrameSchema.from_yaml(yaml_schema)
```

Create DataFrameSchema from yaml file.

Parameters yaml_schema – str, Path to yaml schema, or serialized yaml string.

Return type ForwardRef

Returns dataframe schema.

7.15.1.1.1.6 pandera.schemas.DataFrameSchema.get_dtypes

```
DataFrameSchema.get_dtypes(dataframe)
```

Same as the dtype property, but expands columns where regex == True based on the supplied dataframe.

Return type Dict[str, DataType]

Returns dictionary of columns and their associated dtypes.

7.15.1.1.1.7 pandera.schemas.DataFrameSchema.remove columns

```
DataFrameSchema.remove_columns(cols_to_remove)
```

Removes columns from a DataFrameSchema and returns a new copy.

Parameters cols_to_remove (List) - Columns to be removed from the DataFrameSchema

Return type ForwardRef

Returns a new *DataFrameSchema* without the cols_to_remove

Raises SchemaInitError: if column not in schema.

Example

To remove a column or set of columns from a schema, pass a list of columns to be removed:

```
>>> import pandera as pa
>>>
>>> example_schema = pa.DataFrameSchema(
... {
... "category" : pa.Column(str),
... "probability": pa.Column(float)
... }
... )
```

(continues on next page)

```
>>>
>>> print(example_schema.remove_columns(["category"]))
<Schema DataFrameSchema(
    columns={
        'probability': <Schema Column(name=probability, type=DataType(float64))>
    },
    checks=[],
    coerce=False,
    dtype=None,
    index=None,
    strict=False
    name=None,
    ordered=False,
    unique_column_names=False
)>
```

See also:

add_columns()

7.15.1.1.1.8 pandera.schemas.DataFrameSchema.rename columns

DataFrameSchema.rename_columns(rename_dict)

Rename columns using a dictionary of key-value pairs.

Parameters rename_dict (Dict[str, str]) – dictionary of 'old_name': 'new_name' key-value pairs.

Return type ForwardRef

Returns DataFrameSchema (copy of original)

Raises SchemaInitError if column not in the schema.

Example

To rename a column or set of columns, pass a dictionary of old column names and new column names, similar to the pandas DataFrame method.

```
>>> import pandera as pa
>>>
>>> example_schema = pa.DataFrameSchema({
         "category" : pa.Column(str),
        "probability": pa.Column(float)
. . .
    })
. . .
>>>
>>> print(
        example_schema.rename_columns({
. . .
             "category": "categories",
             "probability": "probabilities"
. . .
        })
...)
<Schema DataFrameSchema(</pre>
    columns={
```

(continues on next page)

```
'categories': <Schema Column(name=categories, type=DataType(str))>
    'probabilities': <Schema Column(name=probabilities,
    type=DataType(float64))>
    },
    checks=[],
    coerce=False,
    dtype=None,
    index=None,
    strict=False
    name=None,
    ordered=False,
    unique_column_names=False
)>
```

See also:

update_column()

7.15.1.1.1.9 pandera.schemas.DataFrameSchema.reset_index

DataFrameSchema.reset_index(level=None, drop=False)

A method for resetting the Index of a DataFrameSchema

Parameters

- level (Optional[List[str]]) list of labels
- **drop** (bool) bool, default True

Return type ForwardRef

Returns a new *DataFrameSchema* with specified column(s) in the index.

Raises SchemaInitError if no index set in schema.

Examples

Similar to the pandas reset_index method on a pandas DataFrame, this method can be used to to fully or partially reset indices of a schema.

To remove the entire index from the schema, just call the reset_index method with default parameters.

(continues on next page)

```
coerce=False,
  dtype=None,
  index=None,
  strict=False
  name=None,
  ordered=False,
  unique_column_names=False
)>
```

This reclassifies an index (or indices) as a column (or columns).

Similarly, to partially alter the index, pass the name of the column you would like to be removed to the level parameter, and you may also decide whether to drop the levels with the drop parameter.

```
example_schema = pa.DataFrameSchema({
        "category" : pa.Column(str)},
        index = pa.MultiIndex([
            pa.Index(name="unique_id1", dtype=int),
. . .
            pa.Index(name="unique_id2", dtype=str)
            ]
. . .
        )
>>> print(example_schema.reset_index(level = ["unique_id1"]))
<Schema DataFrameSchema(
    columns={
        'category': <Schema Column(name=category, type=DataType(str))>
        'unique_id1': <Schema Column(name=unique_id1, type=DataType(int64))>
   },
    checks=[].
    coerce=False,
    dtype=None,
    index=<Schema Index(name=unique_id2, type=DataType(str))>,
    strict=False
   name=None,
    ordered=False,
    unique_column_names=False
)>
```

See also:

set_index()

7.15.1.1.1.10 pandera.schemas.DataFrameSchema.select columns

DataFrameSchema.select_columns(columns)

Select subset of columns in the schema.

New in version 0.4.5

Parameters columns (List[Any]) – list of column names to select.

Return type ForwardRef

Returns DataFrameSchema (copy of original) with only the selected columns.

Raises SchemaInitError if column not in the schema.

Example

To subset a schema by column, and return a new schema:

```
>>> import pandera as pa
>>> example_schema = pa.DataFrameSchema({
        "category" : pa.Column(str),
. . .
        "probability": pa.Column(float)
... })
>>>
>>> print(example_schema.select_columns(['category']))
<Schema DataFrameSchema(
    columns={
        'category': <Schema Column(name=category, type=DataType(str))>
   },
    checks=[],
    coerce=False,
    dtype=None,
    index=None,
    strict=False
   name=None.
    ordered=False,
    unique_column_names=False
```

Note: If an index is present in the schema, it will also be included in the new schema.

7.15.1.1.1.1 pandera.schemas.DataFrameSchema.set_index

DataFrameSchema.set_index(keys, drop=True, append=False)

A method for setting the Index of a DataFrameSchema, via an existing Column or list of columns.

Parameters

```
• keys (List[str]) - list of labels
```

- **drop** (bool) bool, default True
- append (bool) bool, default False

Return type ForwardRef

Returns a new *DataFrameSchema* with specified column(s) in the index.

Raises SchemaInitError if column not in the schema.

Examples

Just as you would set the index in a pandas DataFrame from an existing column, you can set an index within the schema from an existing column in the schema.

```
>>> import pandera as pa
>>>
   example_schema = pa.DataFrameSchema({
>>>
        "category" : pa.Column(str),
. . .
        "probability": pa.Column(float)})
. . .
>>>
>>> print(example_schema.set_index(['category']))
<Schema DataFrameSchema(
    columns={
        'probability': <Schema Column(name=probability, type=DataType(float64))>
    },
    checks=[].
    coerce=False,
    dtype=None,
    index=<Schema Index(name=category, type=DataType(str))>,
    strict=False
    name=None,
    ordered=False.
    unique_column_names=False
)>
```

If you have an existing index in your schema, and you would like to append a new column as an index to it (yielding a Multiindex), just use set_index as you would in pandas.

```
>>> example_schema = pa.DataFrameSchema(
        {
. . .
            "column1": pa.Column(str),
. . .
            "column2": pa.Column(int)
. . .
        index=pa.Index(name = "column3", dtype = int)
...)
>>>
>>> print(example_schema.set_index(["column2"], append = True))
<Schema DataFrameSchema(
    columns={
        'column1': <Schema Column(name=column1, type=DataType(str))>
    },
    checks=[],
    coerce=False.
    dtype=None,
    index=<Schema MultiIndex(</pre>
        indexes=[
            <Schema Index(name=column3, type=DataType(int64))>
            <Schema Index(name=column2, type=DataType(int64))>
        coerce=False,
        strict=False,
        name=None,
        ordered=True
    )>,
    strict=False
    name=None,
    ordered=False,

)>
```

See also:

reset_index()

7.15.1.1.1.12 pandera.schemas.DataFrameSchema.strategy

```
DataFrameSchema.strategy(*, size=None, n_regex_columns=1)
```

Create a hypothesis strategy for generating a DataFrame.

Parameters

- **size** (Optional[int]) number of elements to generate
- n_regex_columns (int) number of regex columns to generate.

Returns a strategy that generates pandas DataFrame objects.

7.15.1.1.13 pandera.schemas.DataFrameSchema.to script

```
DataFrameSchema.to_script(fp=None)
```

Create DataFrameSchema from yaml file.

Parameters path – str, Path to write script

Return type ForwardRef

Returns dataframe schema.

7.15.1.1.1.14 pandera.schemas.DataFrameSchema.to_yaml

```
\label{eq:decomposition} \begin{split} \text{DataFrameSchema.to\_yaml} & (\textit{stream: None} = \textit{None}) \rightarrow \text{str} \\ \text{DataFrameSchema.to\_yaml} & (\textit{stream: os.PathLike}) \rightarrow \text{None} \\ \end{split}
```

Write DataFrameSchema to yaml file.

Parameters stream (Optional[PathLike]) – file stream to write to. If None, dumps to string.

Return type Optional[str]

Returns yaml string if stream is None, otherwise returns None.

7.15.1.1.1.15 pandera.schemas.DataFrameSchema.update_column

```
DataFrameSchema.update_column(column_name, **kwargs)
```

Create copy of a *DataFrameSchema* with updated column properties.

Parameters

- column_name (str) -
- **kwargs** key-word arguments supplied to *Column*

Return type ForwardRef

Returns a new *DataFrameSchema* with updated column

Raises SchemaInitError: if column not in schema or you try to change the name.

Example

Calling schema. 1 returns the *DataFrameSchema* with the updated column.

```
>>> import pandera as pa
>>>
>>> example_schema = pa.DataFrameSchema({
        "category" : pa.Column(str),
        "probability": pa.Column(float)
. . .
... })
>>> print(
        example_schema.update_column(
            'category', dtype=pa.Category
. . .
...)
<Schema DataFrameSchema(
    columns={
        'category': <Schema Column(name=category, type=DataType(category))>
        'probability': <Schema Column(name=probability, type=DataType(float64))>
    },
    checks=[],
    coerce=False,
    dtype=None,
    index=None,
    strict=False
    name=None,
    ordered=False,
    unique_column_names=False
)>
```

See also:

rename_columns()

7.15.1.1.1.16 pandera.schemas.DataFrameSchema.update_columns

DataFrameSchema.update_columns(update_dict)

Create copy of a DataFrameSchema with updated column properties.

```
Parameters update_dict (Dict[str, Dict[str, Any]]) -
```

Return type ForwardRef

Returns a new *DataFrameSchema* with updated columns

Raises *SchemaInitError*: if column not in schema or you try to change the name.

Example

Calling schema.update_columns returns the DataFrameSchema with the updated columns.

```
>>> import pandera as pa
>>>
```

(continues on next page)

```
example_schema = pa.DataFrameSchema({
        "category" : pa.Column(str),
        "probability": pa.Column(float)
. . .
... })
>>>
>>> print(
        example_schema.update_columns(
            {"category": {"dtype":pa.Category}}
. . .
. . .
...)
<Schema DataFrameSchema(
    columns={
        'category': <Schema Column(name=category, type=DataType(category))>
        'probability': <Schema Column(name=probability, type=DataType(float64))>
   },
    checks=[],
    coerce=False,
    dtype=None,
    index=None,
    strict=False
    name=None.
    ordered=False,
    unique_column_names=False
)>
```

7.15.1.1.17 pandera.schemas.DataFrameSchema.validate

DataFrameSchema.validate(check_obj, head=None, tail=None, sample=None, random_state=None, lazy=False, inplace=False)

Check if all columns in a dataframe have a column in the Schema.

Parameters

- **check_obj** (*pd.DataFrame*) the dataframe to be validated.
- **head** (Optional[int]) validate the first n rows. Rows overlapping with *tail* or *sample* are de-duplicated.
- **tail** (Optional[int]) validate the last n rows. Rows overlapping with *head* or *sample* are de-duplicated.
- **sample** (Optional[int]) validate a random sample of n rows. Rows overlapping with *head* or *tail* are de-duplicated.
- random_state (Optional[int]) random seed for the sample argument.
- lazy (bool) if True, lazily evaluates dataframe against all validation checks and raises a SchemaErrors. Otherwise, raise SchemaError as soon as one occurs.
- **inplace** (bool) if True, applies coercion to the object of validation, otherwise creates a copy of the data.

Return type DataFrame

Returns validated DataFrame

Raises SchemaError – when DataFrame violates built-in or custom checks.

Example

Calling schema.validate returns the dataframe.

```
>>> import pandas as pd
>>> import pandera as pa
>>>
>>> df = pd.DataFrame({
        "probability": [0.1, 0.4, 0.52, 0.23, 0.8, 0.76],
. . .
        "category": ["dog", "dog", "cat", "duck", "dog", "dog"]
. . .
   })
. . .
>>>
>>>
    schema_withchecks = pa.DataFrameSchema({
        "probability": pa.Column(
            float, pa.Check(lambda s: (s \ge 0) \& (s \le 1))),
        # check that the "category" column contains a few discrete
        # values, and the majority of the entries are dogs.
. . .
        "category": pa.Column(
. . .
            str, [
                 pa.Check(lambda s: s.isin(["dog", "cat", "duck"])),
. . .
                 pa.Check(lambda s: (s == "dog").mean() > 0.5),
. . .
            ]),
. . .
... })
>>>
>>> schema_withchecks.validate(df)[["probability", "category"]]
   probability category
          0.10
0
                     dog
          0.40
1
                     dog
2
          0.52
                     cat
3
          0.23
                    duck
4
          0.80
                     dog
5
          0.76
                     doa
```

7.15.1.1.1.18 pandera.schemas.DataFrameSchema. call

DataFrameSchema.__call__(dataframe, head=None, tail=None, sample=None, random_state=None, lazy=False, inplace=False)

Alias for DataFrameSchema.validate() method.

Parameters

- **dataframe** (pd. DataFrame) the dataframe to be validated.
- **head** (*int*) validate the first n rows. Rows overlapping with *tail* or *sample* are deduplicated.
- tail (int) validate the last n rows. Rows overlapping with head or sample are deduplicated.
- **sample** (Optional[int]) validate a random sample of n rows. Rows overlapping with *head* or *tail* are de-duplicated.
- random_state (Optional[int]) random seed for the sample argument.

- lazy (bool) if True, lazily evaluates dataframe against all validation checks and raises a SchemaErrors. Otherwise, raise SchemaError as soon as one occurs.
- **inplace** (bool) if True, applies coercion to the object of validation, otherwise creates a copy of the data.

7.15.1.1.2 pandera.schemas.SeriesSchema

Series validator.

Initialize series schema base object.

Parameters

- **dtype** (Union[str, type, *DataType*, Type, ExtensionDtype, dtype, None]) datatype of the column. If a string is specified, then assumes one of the valid pandas string values: http://pandas.pydata.org/pandas-docs/stable/basics.html#dtypes
- checks (Union[Check, Hypothesis, List[Union[Check, Hypothesis]], None]) If element_wise is True, then callable signature should be:

Callable[Any, bool] where the Any input is a scalar element in the column. Otherwise, the input is assumed to be a pandas. Series object.

- **index** specify the datatypes and properties of the index.
- **nullable** (bool) Whether or not column can contain null values.
- unique (bool) Whether or not column can contain duplicate values.
- **coerce** (bool) If True, when schema.validate is called the column will be coerced into the specified dtype. This has no effect on columns where dtype=None.
- name (Optional[str]) series name.
- **title** (Optional[str]) A human-readable label for the series.
- **description** (Optional[str]) An arbitrary textual description of the series.

Attributes

checks	Return list of checks or hypotheses.
coerce	Whether to coerce series to specified type.
description	An arbitrary textual description of the series.
dtype	Get the pandas dtype
name	Get SeriesSchema name.
nullable	Whether the series is nullable.
title	A human-readable label for the series.
unique	Whether to check for duplicates in check object

Methods

init	Initialize series schema base object.
validate	Validate a Series object.
call	Alias for SeriesSchema.validate() method.

7.15.1.1.2.1 pandera.schemas.SeriesSchema.__init__

SeriesSchema.__init__(dtype=None, checks=None, index=None, nullable=False, unique=False, coerce=False, name=None, title=None, description=None)

Initialize series schema base object.

Parameters

- **dtype** (Union[str, type, *DataType*, Type, ExtensionDtype, dtype, None]) datatype of the column. If a string is specified, then assumes one of the valid pandas string values: http://pandas.pydata.org/pandas-docs/stable/basics.html#dtypes
- **checks** (Union[Check, Hypothesis, List[Union[Check, Hypothesis]], None]) If element_wise is True, then callable signature should be:

Callable[Any, bool] where the Any input is a scalar element in the column. Otherwise, the input is assumed to be a pandas. Series object.

- **index** specify the datatypes and properties of the index.
- **nullable** (bool) Whether or not column can contain null values.
- **unique** (bool) Whether or not column can contain duplicate values.
- **coerce** (bool) If True, when schema.validate is called the column will be coerced into the specified dtype. This has no effect on columns where dtype=None.
- name (Optional[str]) series name.
- **title** (Optional[str]) A human-readable label for the series.
- **description** (Optional[str]) An arbitrary textual description of the series.

7.15.1.1.2.2 pandera.schemas.SeriesSchema.validate

SeriesSchema.validate(check_obj, head=None, tail=None, sample=None, random_state=None, lazy=False, inplace=False)

Validate a Series object.

Parameters

- **check_obj** (Series) One-dimensional ndarray with axis labels (including time series).
- **head** (Optional[int]) validate the first n rows. Rows overlapping with *tail* or *sample* are de-duplicated.
- **tail** (Optional[int]) validate the last n rows. Rows overlapping with *head* or *sample* are de-duplicated.
- **sample** (Optional[int]) validate a random sample of n rows. Rows overlapping with *head* or *tail* are de-duplicated.
- random_state (Optional[int]) random seed for the sample argument.

- lazy (bool) if True, lazily evaluates dataframe against all validation checks and raises a SchemaErrors. Otherwise, raise SchemaError as soon as one occurs.
- **inplace** (bool) if True, applies coercion to the object of validation, otherwise creates a copy of the data.

Return type Series

Returns validated Series.

Raises SchemaError – when DataFrame violates built-in or custom checks.

Example

```
>>> import pandas as pd
>>> import pandera as pa
>>>
>>> series_schema = pa.SeriesSchema(
        float, [
. . .
            pa.Check(lambda s: s > 0),
            pa.Check(lambda s: s < 1000),
            pa.Check(lambda s: s.mean() > 300),
        ])
>>> series = pd.Series([1, 100, 800, 900, 999], dtype=float)
>>> print(series_schema.validate(series))
0
       1.0
1
     100.0
2
     800.0
3
     900.0
     999.0
dtype: float64
```

7.15.1.1.2.3 pandera.schemas.SeriesSchema.__call__

SeriesSchema.__call__(check_obj, head=None, tail=None, sample=None, random_state=None, lazy=False, inplace=False)

Alias for SeriesSchema.validate() method.

Return type Series

7.15.1.2 Schema Components

pandera.schema_components.Column	Validate types and properties of DataFrame columns.
pandera.schema_components.Index	Validate types and properties of a DataFrame Index.
pandera.schema_components.MultiIndex	Validate types and properties of a DataFrame MultiIn-
	dex.

7.15.1.2.1 pandera.schema components.Column

Validate types and properties of DataFrame columns.

Create column validator object.

Parameters

- dtype (Union[str, type, DataType, Type, ExtensionDtype, dtype, None]) datatype
 of the column. The datatype for type-checking a dataframe. If a string is specified, then
 assumes one of the valid pandas string values: http://pandas.pydata.org/pandas-docs/stable/
 basics.html#dtypes
- checks (Union[Check, Hypothesis, List[Union[Check, Hypothesis]], None]) checks to verify validity of the column
- nullable (bool) Whether or not column can contain null values.
- unique (bool) whether column values should be unique
- **coerce** (bool) If True, when schema.validate is called the column will be coerced into the specified dtype. This has no effect on columns where dtype=None.
- required (bool) Whether or not column is allowed to be missing
- name (Union[str, Tuple[str, ...], None]) column name in dataframe to validate.
- **regex** (bool) whether the name attribute should be treated as a regex pattern to apply to multiple columns in a dataframe.
- **title** (Optional[str]) A human-readable label for the column.
- **description** (Optional[str]) An arbitrary textual description of the column.

Raises SchemaInitError – if impossible to build schema from parameters

Example

```
>>> import pandas as pd
>>> import pandera as pa
>>>
>>>
>>>
>>>
>>>
>>> schema = pa.DataFrameSchema({
...     "column": pa.Column(str)
... })
>>>
>>> schema.validate(pd.DataFrame({"column": ["foo", "bar"]}))
column
0 foo
1 bar
```

See *here* for more usage details.

Attributes

checks	Return list of checks or hypotheses.
coerce	Whether to coerce series to specified type.
description	An arbitrary textual description of the series.
dtype	Get the pandas dtype
name	Get SeriesSchema name.
nullable	Whether the series is nullable.
properties	Get column properties.
regex	True if name attribute should be treated as a regex
	pattern.
title	A human-readable label for the series.
unique	Whether to check for duplicates in check object

Methods

Create column validator object.
Coerce dtype of a column, handling duplicate column
names.
Generate an example of a particular size.
Get matching column names based on regex column
name pattern.
Used to set or modify the name of a column object.
Create a hypothesis strategy for generating a Col-
umn.
Generate column data object for use by DataFrame
strategy.
Validate a Column in a DataFrame object.
Alias for validate method.

7.15.1.2.1.1 pandera.schema components.Column. init

Column.__init__(dtype=None, checks=None, nullable=False, unique=False, coerce=False, required=True, name=None, regex=False, title=None, description=None)

Create column validator object.

Parameters

- **dtype** (Union[str, type, *DataType*, Type, ExtensionDtype, dtype, None]) datatype of the column. The datatype for type-checking a dataframe. If a string is specified, then assumes one of the valid pandas string values: http://pandas.pydata.org/pandas-docs/stable/basics.html#dtypes
- checks (Union[Check, Hypothesis, List[Union[Check, Hypothesis]], None]) checks to verify validity of the column
- nullable (bool) Whether or not column can contain null values.
- unique (bool) whether column values should be unique
- **coerce** (bool) If True, when schema.validate is called the column will be coerced into the specified dtype. This has no effect on columns where dtype=None.

- required (bool) Whether or not column is allowed to be missing
- name (Union[str, Tuple[str, ...], None]) column name in dataframe to validate.
- **regex** (bool) whether the name attribute should be treated as a regex pattern to apply to multiple columns in a dataframe.
- title (Optional[str]) A human-readable label for the column.
- **description** (Optional[str]) An arbitrary textual description of the column.

Raises SchemaInitError – if impossible to build schema from parameters

Example

See *here* for more usage details.

7.15.1.2.1.2 pandera.schema_components.Column.coerce_dtype

```
Column.coerce_dtype(obj)
```

Coerce dtype of a column, handling duplicate column names.

7.15.1.2.1.3 pandera.schema_components.Column.example

```
Column.example(size=None)
```

Generate an example of a particular size.

Parameters size – number of elements in the generated Index.

Return type DataFrame

Returns pandas DataFrame object.

7.15.1.2.1.4 pandera.schema_components.Column.get_regex_columns

Column.get_regex_columns(columns)

Get matching column names based on regex column name pattern.

Parameters columns (Union[Index, MultiIndex]) - columns to regex pattern match

Return type Union[Index, MultiIndex]

Returns matchin columns

7.15.1.2.1.5 pandera.schema_components.Column.set_name

Column.set_name(name)

Used to set or modify the name of a column object.

Parameters name (str) – the name of the column object

7.15.1.2.1.6 pandera.schema_components.Column.strategy

Column.strategy(*, size=None)

Create a hypothesis strategy for generating a Column.

Parameters size – number of elements to generate

Returns a dataframe strategy for a single column.

7.15.1.2.1.7 pandera.schema_components.Column.strategy_component

Column.strategy_component()

Generate column data object for use by DataFrame strategy.

7.15.1.2.1.8 pandera.schema_components.Column.validate

Column.validate(check_obj, head=None, tail=None, sample=None, random_state=None, lazy=False, inplace=False)

Validate a Column in a DataFrame object.

Parameters

- **check_obj** (DataFrame) pandas DataFrame to validate.
- **head** (Optional[int]) validate the first n rows. Rows overlapping with *tail* or *sample* are de-duplicated.
- **tail** (Optional[int]) validate the last n rows. Rows overlapping with *head* or *sample* are de-duplicated.
- **sample** (Optional[int]) validate a random sample of n rows. Rows overlapping with *head* or *tail* are de-duplicated.
- random_state (Optional[int]) random seed for the sample argument.
- lazy (bool) if True, lazily evaluates dataframe against all validation checks and raises a SchemaErrors. Otherwise, raise SchemaError as soon as one occurs.

• **inplace** (bool) – if True, applies coercion to the object of validation, otherwise creates a copy of the data.

Return type DataFrame

Returns validated DataFrame.

7.15.1.2.1.9 pandera.schema components.Column. call

Column.__call__(check_obj, head=None, tail=None, sample=None, random_state=None, lazy=False, inplace=False)

Alias for validate method.

Return type Union[DataFrame, Series]

7.15.1.2.2 pandera.schema components.Index

class pandera.schema_components.**Index**(dtype=None, checks=None, nullable=False, unique=False, coerce=False, name=None, title=None, description=None)

Validate types and properties of a DataFrame Index.

Initialize series schema base object.

Parameters

- **dtype** (Union[str, type, *DataType*, Type, ExtensionDtype, dtype, None]) datatype of the column. If a string is specified, then assumes one of the valid pandas string values: http://pandas.pydata.org/pandas-docs/stable/basics.html#dtypes
- **checks** (Union[Check, Hypothesis, List[Union[Check, Hypothesis]], None]) If element wise is True, then callable signature should be:
 - Callable[Any, bool] where the Any input is a scalar element in the column. Otherwise, the input is assumed to be a pandas. Series object.
- **nullable** (*bool*) Whether or not column can contain null values.
- unique (bool) Whether or not column can contain duplicate values.
- **coerce** (bool) If True, when schema.validate is called the column will be coerced into the specified dtype. This has no effect on columns where dtype=None.
- name (Optional[Any]) column name in dataframe to validate.
- **title** (Optional[str]) A human-readable label for the series.
- **description** (Optional[str]) An arbitrary textual description of the series.

Attributes

checks	Return list of checks or hypotheses.
coerce	Whether to coerce series to specified type.
description	An arbitrary textual description of the series.
dtype	Get the pandas dtype
name	Get SeriesSchema name.
names	Get index names in the Index schema component.
nullable	Whether the series is nullable.
title	A human-readable label for the series.
unique	Whether to check for duplicates in check object

Methods

example	Generate an example of a particular size.
strategy	Create a hypothesis strategy for generating an In-
	dex.
strategy_component	Generate column data object for use by MultiIndex
	strategy.
validate	Validate DataFrameSchema or SeriesSchema Index.
call	Alias for validate method.

7.15.1.2.2.1 pandera.schema_components.Index.example

Index.example(size=None)

Generate an example of a particular size.

Parameters size (Optional[int]) – number of elements in the generated Index.

Return type Index

Returns pandas Index object.

7.15.1.2.2.2 pandera.schema_components.Index.strategy

Index.strategy(*, size=None)

Create a hypothesis strategy for generating an Index.

Parameters size (Optional[int]) – number of elements to generate.

Returns index strategy.

7.15.1.2.2.3 pandera.schema_components.Index.strategy_component

Index.strategy_component()

Generate column data object for use by MultiIndex strategy.

7.15.1.2.2.4 pandera.schema_components.Index.validate

Validate DataFrameSchema or SeriesSchema Index.

Check_obj pandas DataFrame of Series containing index to validate.

Parameters

- **head** (Optional[int]) validate the first n rows. Rows overlapping with *tail* or *sample* are de-duplicated.
- **tail** (Optional[int]) validate the last n rows. Rows overlapping with *head* or *sample* are de-duplicated.
- **sample** (Optional[int]) validate a random sample of n rows. Rows overlapping with *head* or *tail* are de-duplicated.
- random_state (Optional[int]) random seed for the sample argument.
- lazy (bool) if True, lazily evaluates dataframe against all validation checks and raises a SchemaErrors. Otherwise, raise SchemaError as soon as one occurs.
- **inplace** (bool) if True, applies coercion to the object of validation, otherwise creates a copy of the data.

Return type Union[DataFrame, Series]

Returns validated DataFrame or Series.

7.15.1.2.2.5 pandera.schema components.Index. call

Alias for validate method.

Return type Union[DataFrame, Series]

7.15.1.2.3 pandera.schema components.MultiIndex

Validate types and properties of a DataFrame MultiIndex.

This class inherits from DataFrameSchema to leverage its validation logic.

Create MultiIndex validator.

Parameters

• indexes (List[Index]) – list of Index validators for each level of the MultiIndex index.

- **coerce** (bool) Whether or not to coerce the MultiIndex to the specified dtypes before validation
- **strict** (bool) whether or not to accept columns in the MultiIndex that aren't defined in the indexes argument.
- name (Optional[str]) name of schema component
- **ordered** (bool) whether or not to validate the indexes order.
- **unique** (Union[str, List[str], None]) a list of index names that should be jointly unique.

Example

```
>>> import pandas as pd
>>> import pandera as pa
>>>
>>>
>>> schema = pa.DataFrameSchema(
        columns={"column": pa.Column(int)},
        index=pa.MultiIndex([
. . .
            pa.Index(str,
                   pa.Check(lambda s: s.isin(["foo", "bar"])),
                   name="index0"),
            pa.Index(int, name="index1"),
        ])
...)
>>>
>>> df = pd.DataFrame(
        data={"column": [1, 2, 3]},
. . .
        index=pd.MultiIndex.from_arrays(
. . .
             [["foo", "bar", "foo"], [0, 1, 2]],
. . .
            names=["index0", "index1"],
        )
. . .
...)
>>>
>>> schema.validate(df)
                column
index0 index1
foo
       0
                     1
       1
                     2
bar
foo
       2
                     3
```

See *here* for more usage details.

Attributes

coerce	Whether or not to coerce data types.
description	An arbitrary textual description of the schema.
dtype	Get the dtype property.
dtypes	A dict where the keys are column names and values
	are DataType s for the column.
names	Get index names in the MultiIndex schema compo-
	nent.
ordered	nent. Whether or not to validate the columns order.
ordered title	
	Whether or not to validate the columns order.
title	Whether or not to validate the columns order. A human-readable label for the schema.

Methods

init	Create MultiIndex validator.
coerce_dtype	Coerce type of a pd.Series by type specified in dtype.
example	Generate an example of a particular size.
strategy	Create a hypothesis strategy for generating a
	DataFrame.
validate	Validate DataFrame or Series MultiIndex.
call	Alias for DataFrameSchema.validate() method.

7.15.1.2.3.1 pandera.schema_components.MultiIndex.__init__

MultiIndex.__init__(indexes, coerce=False, strict=False, name=None, ordered=True, unique=None)
Create MultiIndex validator.

Parameters

- indexes (List[Index]) list of Index validators for each level of the MultiIndex index.
- **coerce** (bool) Whether or not to coerce the MultiIndex to the specified dtypes before validation
- **strict** (bool) whether or not to accept columns in the MultiIndex that aren't defined in the indexes argument.
- name (Optional[str]) name of schema component
- **ordered** (bool) whether or not to validate the indexes order.
- **unique** (Union[str, List[str], None]) a list of index names that should be jointly unique.

Example

```
>>> import pandas as pd
>>> import pandera as pa
>>>
>>>
>>>
```

(continues on next page)

```
>>> schema = pa.DataFrameSchema(
        columns={"column": pa.Column(int)},
        index=pa.MultiIndex([
. . .
            pa.Index(str,
. . .
                   pa.Check(lambda s: s.isin(["foo", "bar"])),
                   name="index0"),
             pa.Index(int, name="index1"),
        ])
. . .
    )
. . .
>>>
>>> df = pd.DataFrame(
        data={"column": [1, 2, 3]},
. . .
        index=pd.MultiIndex.from_arrays(
             [["foo", "bar", "foo"], [0, 1, 2]],
. . .
             names=["index0", "index1"],
. . .
. . .
    )
>>>
>>> schema.validate(df)
                column
index0 index1
foo
       0
                      1
bar
       1
                     2
foo
       2
                     3
```

See *here* for more usage details.

7.15.1.2.3.2 pandera.schema_components.MultiIndex.coerce_dtype

```
MultiIndex.coerce_dtype(obj)
```

Coerce type of a pd.Series by type specified in dtype.

Parameters obj (MultiIndex) - multi-index to coerce.

Return type MultiIndex

Returns MultiIndex with coerced data type

7.15.1.2.3.3 pandera.schema components.MultiIndex.example

```
MultiIndex.example(size=None)
```

Generate an example of a particular size.

Parameters size – number of elements in the generated DataFrame.

Return type MultiIndex

Returns pandas DataFrame object.

7.15.1.2.3.4 pandera.schema_components.MultiIndex.strategy

MultiIndex.strategy(*, size=None)

Create a hypothesis strategy for generating a DataFrame.

Parameters

- **size** number of elements to generate
- **n_regex_columns** number of regex columns to generate.

Returns a strategy that generates pandas DataFrame objects.

7.15.1.2.3.5 pandera.schema_components.MultiIndex.validate

MultiIndex.validate(check_obj, head=None, tail=None, sample=None, random_state=None, lazy=False, inplace=False)

Validate DataFrame or Series MultiIndex.

Parameters

- check_obj (Union[DataFrame, Series]) pandas DataFrame of Series to validate.
- **head** (Optional[int]) validate the first n rows. Rows overlapping with *tail* or *sample* are de-duplicated.
- **tail** (Optional[int]) validate the last n rows. Rows overlapping with *head* or *sample* are de-duplicated.
- **sample** (Optional[int]) validate a random sample of n rows. Rows overlapping with *head* or *tail* are de-duplicated.
- random_state (Optional[int]) random seed for the sample argument.
- lazy (bool) if True, lazily evaluates dataframe against all validation checks and raises a SchemaErrors. Otherwise, raise SchemaError as soon as one occurs.
- **inplace** (bool) if True, applies coercion to the object of validation, otherwise creates a copy of the data.

Return type Union[DataFrame, Series]

Returns validated DataFrame or Series.

7.15.1.2.3.6 pandera.schema components.MultiIndex. call

MultiIndex.__call__(dataframe, head=None, tail=None, sample=None, random_state=None, lazy=False, inplace=False)

Alias for DataFrameSchema.validate() method.

Parameters

- **dataframe** (*pd.DataFrame*) the dataframe to be validated.
- **head** (*int*) validate the first n rows. Rows overlapping with *tail* or *sample* are deduplicated.
- tail (int) validate the last n rows. Rows overlapping with head or sample are deduplicated.

- **sample** (Optional[int]) validate a random sample of n rows. Rows overlapping with *head* or *tail* are de-duplicated.
- random_state (Optional[int]) random seed for the sample argument.
- lazy (bool) if True, lazily evaluates dataframe against all validation checks and raises a SchemaErrors. Otherwise, raise SchemaError as soon as one occurs.
- **inplace** (bool) if True, applies coercion to the object of validation, otherwise creates a copy of the data.

7.15.1.3 Checks

pandera.checks.Check	Check a pandas Series or DataFrame for certain proper-
	ties.
pandera.hypotheses.Hypothesis	Special type of Check that defines hypothesis tests on
	data.

7.15.1.3.1 pandera.checks.Check

Check a pandas Series or DataFrame for certain properties.

Apply a validation function to each element, Series, or DataFrame.

Parameters

• check_fn (Union[Callable[[Series], Union[Series, bool]], Callable[[DataFrame], Union[DataFrame, Series, bool]]]) — A function to check pandas data structure. For Column or SeriesSchema checks, if element_wise is True, this function should have the signature: Callable[[pd.Series], Union[pd.Series, bool]], where the output series is a boolean vector.

If element_wise is False, this function should have the signature: Callable[[Any], bool], where Any is an element in the column.

For DataFrameSchema checks, if element_wise=True, fn should have the signature: Callable[[pd.DataFrame], Union[pd.DataFrame, pd.Series, bool]], where the output dataframe or series contains booleans.

If element_wise is True, fn is applied to each row in the dataframe with the signature Callable[[pd.Series], bool] where the series input is a row in the dataframe.

- **groups** (Union[str, List[str], None]) The dict input to the *fn* callable will be constrained to the groups specified by *groups*.
- **groupby** (Union[str, List[str], Callable, None]) If a string or list of strings is provided, these columns are used to group the Column series. If a callable is passed, the expected signature is: Callable[[pd.DataFrame], pd.core.groupby.DataFrameGroupBy]

The the case of Column checks, this function has access to the entire dataframe, but Column. name is selected from this DataFrameGroupby object so that a SeriesGroupBy object is passed into check_fn.

Specifying the groupby argument changes the check_fn signature to:

```
Callable[[Dict[Union[str, Tuple[str]], pd.Series]], Union[bool, pd.
Series]] # noqa
```

where the input is a dictionary mapping keys to subsets of the column/dataframe.

- **ignore_na** (bool) If True, null values will be ignored when determining if a check passed or failed. For dataframes, ignores rows with any null value. *New in version 0.4.0*
- **element_wise** (bool) Whether or not to apply validator in an element-wise fashion. If bool, assumes that all checks should be applied to the column element-wise. If list, should be the same number of elements as checks.
- name (Optional[str]) optional name for the check.
- **error** (Optional[str]) custom error message if series fails validation check.
- raise_warning (bool) if True, raise a UserWarning and do not throw exception instead of raising a SchemaError for a specific check. This option should be used carefully in cases where a failing check is informational and shouldn't stop execution of the program.
- n_failure_cases (Optional[int]) report the first n unique failure cases. If None, report all failure cases.
- title (Optional[str]) A human-readable label for the check.
- **description** (Optional[str]) An arbitrary textual description of the check.
- **check_kwargs** key-word arguments to pass into **check_fn**

Example

```
>>> import pandas as pd
>>> import pandera as pa
>>>
>>>
>>> # column checks are vectorized by default
>>> check_positive = pa.Check(lambda s: s > 0)
>>>
>>> # define an element-wise check
>>> check_even = pa.Check(lambda x: x % 2 == 0, element_wise=True)
>>>
>>> # checks can be given human-readable metadata
>>> check_with_metadata = pa.Check(
        lambda x: True,
        title="Always passes",
. . .
        description="This check always passes."
. . .
...)
>>>
>>> # specify assertions across categorical variables using `groupby`,
>>> # for example, make sure the mean measure for group "A" is always
>>> # larger than the mean measure for group "B"
>>> check_by_group = pa.Check(
        lambda measures: measures["A"].mean() > measures["B"].mean(),
. . .
        groupby=["group"],
. . .
. . .
>>>
>>> # define a wide DataFrame-level check
>>> check_dataframe = pa.Check(
        lambda df: df["measure_1"] > df["measure_2"])
. . .
```

(continues on next page)

```
>>>
>>> measure_checks = [check_positive, check_even, check_by_group]
>>>
>>> schema = pa.DataFrameSchema(
        columns={
            "measure_1": pa.Column(int, checks=measure_checks),
. . .
            "measure_2": pa.Column(int, checks=measure_checks),
            "group": pa.Column(str),
        },
        checks=check_dataframe
. . .
...)
>>>
>>> df = pd.DataFrame({
        "measure_1": [10, 12, 14, 16],
        "measure_2": [2, 4, 6, 8],
        "group": ["B", "B", "A", "A"]
. . .
... })
>>>
>>> schema.validate(df)[["measure_1", "measure_2", "group"]]
    measure_1 measure_2 group
                       2
0
          10
1
          12
                       4
                             В
2
          14
                       6
                             Α
3
          16
                       8
                             Α
```

See here for more usage details.

Attributes

statistics	Get check statistics.
REGISTERED_CUSTOM_CHECKS	

Methods

eq	Ensure all elements of a series equal a certain value.
equal_to	Ensure all elements of a series equal a certain value.
ge	Ensure all values are greater or equal a certain value.
greater_than	Ensure values of a series are strictly greater than a
	minimum value.
<pre>greater_than_or_equal_to</pre>	Ensure all values are greater or equal a certain value.
gt	Ensure values of a series are strictly greater than a
	minimum value.
in_range	Ensure all values of a series are within an interval.
isin	Ensure only allowed values occur within a series.
le	Ensure values are less than or equal to a maximum
	value.
less_than	Ensure values of a series are strictly below a maxi-
	mum value.
less_than_or_equal_to	Ensure values are less than or equal to a maximum
	value.
1t	Ensure values of a series are strictly below a maxi-
	mum value.
ne	Ensure no elements of a series equals a certain value.
not_equal_to	Ensure no elements of a series equals a certain value.
notin	Ensure some defined values don't occur within a se-
	ries.
str_contains	Ensure that a pattern can be found within each row.
str_endswith	Ensure that all values end with a certain string.
str_length	Ensure that the length of strings is within a specified
	range.
str_matches	Ensure that string values match a regular expression.
str_startswith	Ensure that all values start with a certain string.
call	Validate pandas DataFrame or Series.

7.15.1.3.1.1 pandera.checks.Check.eq

classmethod Check.eq(cls, value, **kwargs)

Ensure all elements of a series equal a certain value.

New in version 0.4.5 Alias: eq

Parameters

- value All elements of a given pandas. Series must have this value
- kwargs key-word arguments passed into the Check initializer.

Return type Check

Returns Check object

7.15.1.3.1.2 pandera.checks.Check.equal to

classmethod Check.equal_to(cls, value, **kwargs)

Ensure all elements of a series equal a certain value.

New in version 0.4.5 Alias: eq

Parameters

- value All elements of a given pandas. Series must have this value
- **kwargs** key-word arguments passed into the *Check* initializer.

Return type Check

Returns Check object

7.15.1.3.1.3 pandera.checks.Check.ge

classmethod Check.ge(cls, min_value, **kwargs)

Ensure all values are greater or equal a certain value.

New in version 0.4.5 Alias: ge

Parameters

- min_value Allowed minimum value for values of a series. Must be a type comparable to the dtype of the pandas. Series to be validated.
- **kwargs** key-word arguments passed into the *Check* initializer.

Return type Check

Returns Check object

7.15.1.3.1.4 pandera.checks.Check.greater_than

classmethod Check.greater_than(cls, min_value, **kwargs)

Ensure values of a series are strictly greater than a minimum value.

New in version 0.4.5 Alias: gt

Parameters

- min_value Lower bound to be exceeded. Must be a type comparable to the dtype of the pandas. Series to be validated (e.g. a numerical type for float or int and a datetime for datetime).
- **kwargs** key-word arguments passed into the *Check* initializer.

Return type Check

Returns Check object

7.15.1.3.1.5 pandera.checks.Check.greater than or equal to

classmethod Check.greater_than_or_equal_to(cls, min_value, **kwargs)

Ensure all values are greater or equal a certain value.

New in version 0.4.5 Alias: ge

Parameters

- min_value Allowed minimum value for values of a series. Must be a type comparable to the dtype of the pandas. Series to be validated.
- **kwargs** key-word arguments passed into the *Check* initializer.

Return type Check

Returns Check object

7.15.1.3.1.6 pandera.checks.Check.gt

classmethod Check.gt(cls, min_value, **kwargs)

Ensure values of a series are strictly greater than a minimum value.

New in version 0.4.5 Alias: gt

Parameters

- min_value Lower bound to be exceeded. Must be a type comparable to the dtype of the pandas. Series to be validated (e.g. a numerical type for float or int and a datetime for datetime).
- **kwargs** key-word arguments passed into the *Check* initializer.

Return type Check

Returns Check object

7.15.1.3.1.7 pandera.checks.Check.in_range

Ensure all values of a series are within an interval.

Parameters

- min_value Left / lower endpoint of the interval.
- max_value Right / upper endpoint of the interval. Must not be smaller than min_value.
- **include_min** Defines whether min_value is also an allowed value (the default) or whether all values must be strictly greater than min_value.
- **include_max** Defines whether min_value is also an allowed value (the default) or whether all values must be strictly smaller than max_value.
- **kwargs** key-word arguments passed into the *Check* initializer.

Both endpoints must be a type comparable to the dtype of the pandas. Series to be validated.

Return type Check

Returns Check object

7.15.1.3.1.8 pandera.checks.Check.isin

classmethod Check.isin(cls, allowed values, **kwargs)

Ensure only allowed values occur within a series.

Parameters

- allowed_values (Iterable) The set of allowed values. May be any iterable.
- **kwargs** key-word arguments passed into the *Check* initializer.

Return type Check

Returns Check object

Note: It is checked whether all elements of a pandas. Series are part of the set of elements of allowed values. If allowed values is a string, the set of elements consists of all distinct characters of the string. Thus only single characters which occur in allowed_values at least once can meet this condition. If you want to check for substrings use Check.str_is_substring().

7.15.1.3.1.9 pandera.checks.Check.le

classmethod Check.le(cls, max_value, **kwargs)

Ensure values are less than or equal to a maximum value.

New in version 0.4.5 Alias: le

Parameters

- max_value Upper bound not to be exceeded. Must be a type comparable to the dtype of the pandas. Series to be validated.
- **kwargs** key-word arguments passed into the *Check* initializer.

Return type Check

Returns Check object

7.15.1.3.1.10 pandera.checks.Check.less than

classmethod Check.less_than(cls, max_value, **kwargs)

Ensure values of a series are strictly below a maximum value.

New in version 0.4.5 Alias: 1t

Parameters

- max_value All elements of a series must be strictly smaller than this. Must be a type comparable to the dtype of the pandas. Series to be validated.
- **kwargs** key-word arguments passed into the *Check* initializer.

Return type Check

Returns Check object

7.15.1.3.1.11 pandera.checks.Check.less_than_or_equal_to

classmethod Check.less_than_or_equal_to(cls, max_value, **kwargs)

Ensure values are less than or equal to a maximum value.

New in version 0.4.5 Alias: le

Parameters

- max_value Upper bound not to be exceeded. Must be a type comparable to the dtype of the pandas. Series to be validated.
- **kwargs** key-word arguments passed into the *Check* initializer.

Return type Check

Returns Check object

7.15.1.3.1.12 pandera.checks.Check.lt

classmethod Check.lt(cls, max_value, **kwargs)

Ensure values of a series are strictly below a maximum value.

New in version 0.4.5 Alias: 1t

Parameters

- max_value All elements of a series must be strictly smaller than this. Must be a type comparable to the dtype of the pandas. Series to be validated.
- **kwargs** key-word arguments passed into the *Check* initializer.

Return type Check

Returns Check object

7.15.1.3.1.13 pandera.checks.Check.ne

classmethod Check.ne(cls, value, **kwargs)

Ensure no elements of a series equals a certain value.

New in version 0.4.5 Alias: ne

Parameters

- value This value must not occur in the checked pandas. Series.
- **kwargs** key-word arguments passed into the *Check* initializer.

Return type Check

Returns Check object

7.15.1.3.1.14 pandera.checks.Check.not_equal_to

classmethod Check.not_equal_to(cls, value, **kwargs)

Ensure no elements of a series equals a certain value.

New in version 0.4.5 Alias: ne

Parameters

- value This value must not occur in the checked pandas. Series.
- **kwargs** key-word arguments passed into the *Check* initializer.

Return type Check

Returns Check object

7.15.1.3.1.15 pandera.checks.Check.notin

classmethod Check.notin(cls, forbidden_values, **kwargs)

Ensure some defined values don't occur within a series.

Parameters

- **forbidden_values** (Iterable) The set of values which should not occur. May be any iterable.
- raise_warning if True, check raises UserWarning instead of SchemaError on validation.

Return type Check

Returns Check object

Note: Like *Check.isin()* this check operates on single characters if it is applied on strings. A string as paraforbidden_valuesmeter forbidden_values is understood as set of prohibited characters. Any string of length > 1 can't be in it by design.

7.15.1.3.1.16 pandera.checks.Check.str_contains

classmethod Check.str_contains(cls, pattern, **kwargs)

Ensure that a pattern can be found within each row.

Parameters

- pattern (str) Regular expression pattern to use for searching
- **kwargs** key-word arguments passed into the *Check* initializer.

Return type Check

Returns Check object

The behaviour is as of pandas. Series.str.contains().

7.15.1.3.1.17 pandera.checks.Check.str endswith

classmethod Check.str_endswith(cls, string, **kwargs)

Ensure that all values end with a certain string.

Parameters

- **string** (str) String all values should end with
- **kwargs** key-word arguments passed into the *Check* initializer.

Return type Check

Returns Check object

7.15.1.3.1.18 pandera.checks.Check.str_length

```
classmethod Check.str_length(cls, min_value=None, max_value=None, **kwargs)
```

Ensure that the length of strings is within a specified range.

Parameters

- min_value (Optional[int]) Minimum length of strings (default: no minimum)
- max_value (Optional[int]) Maximum length of strings (default: no maximum)
- **kwargs** key-word arguments passed into the *Check* initializer.

Return type Check

Returns Check object

7.15.1.3.1.19 pandera.checks.Check.str matches

classmethod Check.str_matches(cls, pattern, **kwargs)

Ensure that string values match a regular expression.

Parameters

- pattern (str) Regular expression pattern to use for matching
- **kwargs** key-word arguments passed into the *Check* initializer.

Return type Check

Returns Check object

The behaviour is as of pandas.Series.str.match().

7.15.1.3.1.20 pandera.checks.Check.str_startswith

classmethod Check.str_startswith(cls, string, **kwargs)

Ensure that all values start with a certain string.

Parameters

- string (str) String all values should start with
- **kwargs** key-word arguments passed into the *Check* initializer.

Return type Check

Returns Check object

7.15.1.3.1.21 pandera.checks.Check.__call__

Check.__call__(*df_or_series*, *column=None*)

Validate pandas DataFrame or Series.

Parameters

- df_or_series (Union[DataFrame, Series]) pandas DataFrame of Series to validate.
- **column** (Optional[str]) for dataframe checks, apply the check function to this column.

Return type CheckResult

Returns

CheckResult tuple containing:

check_output: boolean scalar, Series or DataFrame indicating which elements passed the check.

check_passed: boolean scalar that indicating whether the check passed overall.

checked_object: the checked object itself. Depending on the options provided to the Check, this will be a pandas Series, DataFrame, or if the groupby option is specified, a Dict[str, Series] or Dict[str, DataFrame] where the keys are distinct groups.

failure_cases: subset of the check_object that failed.

7.15.1.3.2 pandera.hypotheses.Hypothesis

Special type of Check that defines hypothesis tests on data.

Perform a hypothesis test on a Series or DataFrame.

Parameters

- **test** (Callable) The hypothesis test function. It should take one or more arrays as positional arguments and return a test statistic and a p-value. The arrays passed into the test function are determined by the samples argument.
- **samples** (Union[str, List[str], None]) for *Column* or *SeriesSchema* hypotheses, this refers to the group keys in the *groupby* column(s) used to group the *Series* into a dict of *Series*. The *samples* column(s) are passed into the *test* function as positional arguments.

For *DataFrame*-level hypotheses, *samples* refers to a column or multiple columns to pass into the *test* function. The *samples* column(s) are passed into the *test* function as positional arguments.

• **groupby** (Union[str, List[str], Callable, None]) – If a string or list of strings is provided, then these columns are used to group the Column Series by *groupby*. If a callable is passed, the expected signature is DataFrame -> DataFrameGroupby. The function has access to the entire dataframe, but the Column.name is selected from this DataFrameGroupby object so that a SeriesGroupBy object is passed into the *hypothesis_check* function.

Specifying this argument changes the fn signature to: dict[str|tuple[str], Series] -> bool|pd.Series[bool]

Where specific groups can be obtained from the input dict.

• **relationship** (Union[str, Callable]) – Represents what relationship conditions are imposed on the hypothesis test. A function or lambda function can be supplied.

Available built-in relationships are: "greater_than", "less_than", "not_equal" or "equal", where "equal" is the null hypothesis.

If callable, the input function signature should have the signature (stat: float, pvalue: float, **kwargs) where *stat* is the hypothesis test statistic, *pvalue* assesses statistical significance, and **kwargs are other arguments supplied via the **relation-ship_kwargs argument.

Default is "equal" for the null hypothesis.

- **test_kwargs** (*dict*) Keyword arguments to be supplied to the test.
- **relationship_kwargs** (*dict*) Keyword arguments to be supplied to the relationship function. e.g. *alpha* could be used to specify a threshold in a t-test.
- name (Optional[str]) optional name of hypothesis test
- **error** (Optional[str]) error message to show
- raise_warning (bool) if True, raise a UserWarning and do not throw exception instead of raising a SchemaError for a specific check. This option should be used carefully in cases where a failing check is informational and shouldn't stop execution of the program.

Examples

Define a two-sample hypothesis test using scipy.

```
>>> import pandas as pd
>>> import pandera as pa
>>>
>>> from scipy import stats
>>>
>>>
    schema = pa.DataFrameSchema({
        "height_in_feet": pa.Column(float, [
             pa.Hypothesis(
. . .
                 test=stats.ttest_ind,
                 samples=["A", "B"],
. . .
                 groupby="group",
                 # assert that the mean height of group "A" is greater
                 # than that of group "B"
                 relationship=lambda stat, pvalue, alpha=0.1: (
. . .
                     stat > 0 and pvalue / 2 < alpha
                 ),
. . .
                 # set alpha criterion to 5%
                 relationship_kwargs={"alpha": 0.05}
. . .
             )
        ]),
. . .
        "group": pa.Column(str),
. . .
... })
>>> df = (
        pd.DataFrame({
. . .
```

(continues on next page)

(continued from previous page)

```
"height_in_feet": [8.1, 7, 5.2, 5.1, 4],
             "group": ["A", "A", "B", "B", "B"]
        })
. . .
...)
>>> schema.validate(df)[["height_in_feet", "group"]]
   height_in_feet group
0
               8.1
               7.0
1
                       Α
2
               5.2
                       В
3
               5.1
                       В

                       В
```

See *here* for more usage details.

Attributes

RELATIONSHIPS	Relationships available for built-in hypothesis tests.
is_one_sample_test	Return True if hypothesis is a one-sample test.
statistics	Get check statistics.
REGISTERED_CUSTOM_CHECKS	

Methods

init	Perform a hypothesis test on a Series or DataFrame.
one_sample_ttest	Calculate a t-test for the mean of one sample.
two_sample_ttest	Calculate a t-test for the means of two samples.
call	Validate pandas DataFrame or Series.

7.15.1.3.2.1 pandera.hypotheses.Hypothesis. init

Hypothesis.__init__(test, samples=None, groupby=None, relationship='equal', test_kwargs=None, relationship_kwargs=None, name=None, error=None, raise_warning=False)

Perform a hypothesis test on a Series or DataFrame.

Parameters

- **test** (Callable) The hypothesis test function. It should take one or more arrays as positional arguments and return a test statistic and a p-value. The arrays passed into the test function are determined by the samples argument.
- **samples** (Union[str, List[str], None]) for *Column* or *SeriesSchema* hypotheses, this refers to the group keys in the *groupby* column(s) used to group the *Series* into a dict of *Series*. The *samples* column(s) are passed into the *test* function as positional arguments.

For *DataFrame*-level hypotheses, *samples* refers to a column or multiple columns to pass into the *test* function. The *samples* column(s) are passed into the *test* function as positional arguments.

• **groupby** (Union[str, List[str], Callable, None]) – If a string or list of strings is provided, then these columns are used to group the Column Series by *groupby*. If a callable is passed, the expected signature is DataFrame -> DataFrameGroupby. The function has access to the entire dataframe, but the Column.name is selected from this DataFrameGroupby object so that a SeriesGroupBy object is passed into the *hypothesis_check* function.

Specifying this argument changes the *fn* signature to: dict[str|tuple[str], Series] -> bool|pd.Series[bool]

Where specific groups can be obtained from the input dict.

• **relationship** (Union[str, Callable]) – Represents what relationship conditions are imposed on the hypothesis test. A function or lambda function can be supplied.

Available built-in relationships are: "greater_than", "less_than", "not_equal" or "equal", where "equal" is the null hypothesis.

If callable, the input function signature should have the signature (stat: float, pvalue: float, **kwargs) where *stat* is the hypothesis test statistic, *pvalue* assesses statistical significance, and **kwargs are other arguments supplied via the **relation-ship_kwargs argument.

Default is "equal" for the null hypothesis.

- test_kwargs (dict) Keyword arguments to be supplied to the test.
- **relationship_kwargs** (*dict*) Keyword arguments to be supplied to the relationship function. e.g. *alpha* could be used to specify a threshold in a t-test.
- name (Optional[str]) optional name of hypothesis test
- error (Optional[str]) error message to show
- raise_warning (bool) if True, raise a UserWarning and do not throw exception instead of raising a SchemaError for a specific check. This option should be used carefully in cases where a failing check is informational and shouldn't stop execution of the program.

Examples

Define a two-sample hypothesis test using scipy.

```
>>> import pandas as pd
>>> import pandera as pa
>>>
>>> from scipy import stats
>>>
>>>
    schema = pa.DataFrameSchema({
         "height_in_feet": pa.Column(float, [
             pa.Hypothesis(
. . .
                 test=stats.ttest_ind,
. . .
                 samples=["A", "B"],
                 groupby="group",
. . .
                 # assert that the mean height of group "A" is greater
. . .
                 # than that of group "B"
. . .
                 relationship=lambda stat, pvalue, alpha=0.1: (
. . .
                      stat > 0 and pvalue / 2 < alpha
. . .
. . .
                 # set alpha criterion to 5%
. . .
                 relationship_kwargs={"alpha": 0.05}
. . .
             )
. . .
```

(continues on next page)

(continued from previous page)

```
]),
        "group": pa.Column(str),
... })
>>> df = (
        pd.DataFrame({
             "height_in_feet": [8.1, 7, 5.2, 5.1, 4],
. . .
             "group": ["A", "A", "B", "B", "B"]
        })
. . .
    )
>>> schema.validate(df)[["height_in_feet", "group"]]
  height_in_feet group
0
               8.1
1
               7.0
                       Α
2
               5.2
                       В
3
                       R
               5.1
4
               4.0
```

See here for more usage details.

7.15.1.3.2.2 pandera.hypotheses.Hypothesis.one sample ttest

Calculate a t-test for the mean of one sample.

Parameters

- **sample** (Optional[str]) The sample group to test. For *Column* and *SeriesSchema* hypotheses, this refers to the *groupby* level that is used to subset the *Column* being checked. For *DataFrameSchema* hypotheses, refers to column in the *DataFrame*.
- **groupby** (Union[str, List[str], Callable, None]) If a string or list of strings is provided, then these columns are used to group the Column Series by *groupby*. If a callable is passed, the expected signature is DataFrame -> DataFrameGroupby. The function has access to the entire dataframe, but the Column.name is selected from this DataFrameGroupby object so that a SeriesGroupBy object is passed into *fn*.

Specifying this argument changes the fn signature to: dict[str|tuple[str], Series] -> bool|pd.Series[bool]

Where specific groups can be obtained from the input dict.

- **popmean** (float) population mean to compare *sample* to.
- **relationship** (str) Represents what relationship conditions are imposed on the hypothesis test. Available relationships are: "greater_than", "less_than", "not_equal" and "equal". For example, *group1 greater_than group2* specifies an alternative hypothesis that the mean of group1 is greater than group 2 relative to a null hypothesis that they are equal.
- alpha (float) (Default value = 0.01) The significance level; the probability of rejecting the null hypothesis when it is true. For example, a significance level of 0.01 indicates a 1% risk of concluding that a difference exists when there is no actual difference.
- raise_warning if True, check raises UserWarning instead of SchemaError on validation.

Example

If you want to compare one sample with a pre-defined mean:

```
>>> import pandas as pd
>>> import pandera as pa
>>>
>>>
    schema = pa.DataFrameSchema({
>>>
        "height_in_feet": pa.Column(
             float. [
. . .
                 pa.Hypothesis.one_sample_ttest(
                     popmean=5,
. . .
                     relationship="greater_than",
                     alpha=0.1),
        ]),
... })
>>> df = (
        pd.DataFrame({
             "height_in_feet": [8.1, 7, 6.5, 6.7, 5.1],
        })
. . .
    )
>>> schema.validate(df)
   height_in_feet
0
               8.1
               7.0
1
2
               6.5
3
               6.7
4
               5.1
```

7.15.1.3.2.3 pandera.hypotheses.Hypothesis.two sample ttest

Calculate a t-test for the means of two samples.

Perform a two-sided test for the null hypothesis that 2 independent samples have identical average (expected) values. This test assumes that the populations have identical variances by default.

Parameters

- **sample1** (str) The first sample group to test. For *Column* and *SeriesSchema* hypotheses, refers to the level in the *groupby* column. For *DataFrameSchema* hypotheses, refers to column in the *DataFrame*.
- **sample2** (str) The second sample group to test. For *Column* and *SeriesSchema* hypotheses, refers to the level in the *groupby* column. For *DataFrameSchema* hypotheses, refers to column in the *DataFrame*.
- **groupby** (Union[str, List[str], Callable, None]) If a string or list of strings is provided, then these columns are used to group the Column Series by *groupby*. If a callable is passed, the expected signature is DataFrame -> DataFrameGroupby. The function has access to the entire dataframe, but the Column.name is selected from this DataFrameGroupby object so that a SeriesGroupBy object is passed into *fn*.

Specifying this argument changes the *fn* signature to: dict[str|tuple[str], Series] -> bool|pd.Series[bool]

Where specific groups can be obtained from the input dict.

- **relationship** (str) Represents what relationship conditions are imposed on the hypothesis test. Available relationships are: "greater_than", "less_than", "not_equal", and "equal". For example, *group1 greater_than group2* specifies an alternative hypothesis that the mean of group1 is greater than group 2 relative to a null hypothesis that they are equal.
- **alpha** (Default value = 0.01) The significance level; the probability of rejecting the null hypothesis when it is true. For example, a significance level of 0.01 indicates a 1% risk of concluding that a difference exists when there is no actual difference.
- equal_var (Default value = True) If True (default), perform a standard independent 2 sample test that assumes equal population variances. If False, perform Welch's t-test, which does not assume equal population variance
- nan_policy Defines how to handle when input returns nan, one of {'propagate', 'raise', 'omit'}, (Default value = 'propagate'). For more details see: https://docs.scipy.org/doc/scipy/reference/generated/scipy.stats.ttest ind.html
- raise_warning if True, check raises UserWarning instead of SchemaError on validation.

Example

The the built-in class method to do a two-sample t-test.

```
import pandera as pa
>>>
>>>
    schema = pa.DataFrameSchema({
>>>
         "height_in_feet": pa.Column(
             float, [
. . .
                  pa.Hypothesis.two_sample_ttest(
. . .
                      sample1="A",
                      sample2="B",
. . .
                      groupby="group",
. . .
                      relationship="greater_than",
                      alpha=0.05,
. . .
                      equal_var=True),
. . .
. . .
         "group": pa.Column(str)
. . .
    })
    df = (
>>>
         pd.DataFrame({
. . .
             "height_in_feet": [8.1, 7, 5.2, 5.1, 4],
             "group": ["A", "A", "B", "B", "B"]
. . .
         })
. . .
. . .
>>> schema.validate(df)[["height_in_feet", "group"]]
   height_in_feet group
0
               8.1
                        Α
1
                7.0
                        Α
2
                5.2
                        В
3
                5.1
                        В
4
                        В
                4.0
```

7.15.1.3.2.4 pandera.hypotheses.Hypothesis.__call__

Hypothesis.__call__(df_or_series, column=None)

Validate pandas DataFrame or Series.

Parameters

- **df_or_series** (Union[DataFrame, Series]) pandas DataFrame of Series to validate.
- **column** (Optional[str]) for dataframe checks, apply the check function to this column.

Return type CheckResult

Returns

CheckResult tuple containing:

check_output: boolean scalar, Series or DataFrame indicating which elements passed the check.

check_passed: boolean scalar that indicating whether the check passed overall.

checked_object: the checked object itself. Depending on the options provided to the Check, this will be a pandas Series, DataFrame, or if the groupby option is specified, a Dict[str, Series] or Dict[str, DataFrame] where the keys are distinct groups.

failure_cases: subset of the check_object that failed.

7.15.2 Data Types

7.15.2.1 Library-agnostic dtypes

pandera.dtypes.DataType	Base class of all Pandera data types.
pandera.dtypes.Bool	Semantic representation of a boolean data type.
pandera.dtypes.Timestamp	Semantic representation of a timestamp data type.
pandera.dtypes.DateTime	alias of pandera.dtypes.Timestamp
pandera.dtypes.Timedelta	Semantic representation of a delta time data type.
pandera.dtypes.Category	Semantic representation of a categorical data type.
pandera.dtypes.Float	Semantic representation of a floating data type.
pandera.dtypes.Float16	Semantic representation of a floating data type stored in 16 bits.
pandera.dtypes.Float32	Semantic representation of a floating data type stored in 32 bits.
pandera.dtypes.Float64	Semantic representation of a floating data type stored in 64 bits.
pandera.dtypes.Float128	Semantic representation of a floating data type stored in 128 bits.
pandera.dtypes.Int	Semantic representation of an integer data type.
pandera.dtypes.Int8	Semantic representation of an integer data type stored in 8 bits.
pandera.dtypes.Int16	Semantic representation of an integer data type stored in 16 bits.
pandera.dtypes.Int32	Semantic representation of an integer data type stored in 32 bits.
pandera.dtypes.Int64	Semantic representation of an integer data type stored in
	64 bits.
pandera.dtypes.UInt	Semantic representation of an unsigned integer data
	type.
pandera.dtypes.UInt8	Semantic representation of an unsigned integer data type stored in 8 bits.
pandera.dtypes.UInt16	Semantic representation of an unsigned integer data type stored in 16 bits.
pandera.dtypes.UInt32	Semantic representation of an unsigned integer data type stored in 32 bits.
pandera.dtypes.UInt64	Semantic representation of an unsigned integer data type stored in 64 bits.
pandera.dtypes.Complex	Semantic representation of a complex number data type.
pandera.dtypes.Complex64	Semantic representation of a complex number data type stored in 64 bits.
pandera.dtypes.Complex128	Semantic representation of a complex number data type stored in 128 bits.
pandera.dtypes.Complex256	Semantic representation of a complex number data type stored in 256 bits.
pandera.dtypes.String	Semantic representation of a string data type.
	1 0 71

7.15.2.1.1 pandera.dtypes.DataType

class pandera.dtypes.DataType

Base class of all Pandera data types.

Attributes

continuous	Whether the number data type is continuous.

Methods

init	
check	Check that pandera <i>DataType</i> are equivalent.
coerce	Coerce data container to the data type.
coerce_value	Coerce an value to a particular type.
try_coerce	Coerce data container to the data type, raises a ~pan-
	dera.errors.ParserError if the coercion fails
call	Coerce data container to the data type.

7.15.2.1.1.1 pandera.dtypes.DataType.__init__

DataType.__init__()

7.15.2.1.1.2 pandera.dtypes.DataType.check

DataType.check(pandera_dtype)

Check that pandera *DataType* are equivalent.

Return type bool

7.15.2.1.1.3 pandera.dtypes.DataType.coerce

DataType.coerce(data_container)

Coerce data container to the data type.

7.15.2.1.1.4 pandera.dtypes.DataType.coerce_value

DataType.coerce_value(value)

Coerce an value to a particular type.

7.15.2.1.1.5 pandera.dtypes.DataType.try_coerce

DataType.try_coerce(data_container)

Coerce data container to the data type, raises a ~pandera.errors.ParserError if the coercion fails

Raises ParserError: if coercion fails

7.15.2.1.1.6 pandera.dtypes.DataType.__call__

DataType.__call__(data_container)

Coerce data container to the data type.

7.15.2.1.2 pandera.dtypes.Bool

class pandera.dtypes.Bool

Semantic representation of a boolean data type.

Attributes

continuous	Whether the number data type is continuous.
exact	Whether the data type is an exact representation of a
	number.

Methods

Check that pandera <i>DataType</i> are equivalent.
Coerce data container to the data type.
Coerce an value to a particular type.
Coerce data container to the data type, raises a ~pan-
dera.errors.ParserError if the coercion fails
Coerce data container to the data type.

7.15.2.1.2.1 pandera.dtypes.Bool.__init__

Bool.__init__()

7.15.2.1.2.2 pandera.dtypes.Bool.check

Bool.check(pandera_dtype)

Check that pandera *DataType* are equivalent.

Return type bool

7.15.2.1.2.3 pandera.dtypes.Bool.coerce

Bool.coerce(data_container)

Coerce data container to the data type.

7.15.2.1.2.4 pandera.dtypes.Bool.coerce_value

Bool.coerce_value(value)

Coerce an value to a particular type.

7.15.2.1.2.5 pandera.dtypes.Bool.try_coerce

Bool.try_coerce(data_container)

Coerce data container to the data type, raises a ~pandera.errors.ParserError if the coercion fails

Raises ParserError: if coercion fails

7.15.2.1.2.6 pandera.dtypes.Bool.__call__

Bool.__call__(data_container)

Coerce data container to the data type.

7.15.2.1.3 pandera.dtypes.Timestamp

class pandera.dtypes.Timestamp

Semantic representation of a timestamp data type.

Attributes

continuous

Whether the number data type is continuous.

Methods

init	
check	Check that pandera <i>DataType</i> are equivalent.
coerce	Coerce data container to the data type.
coerce_value	Coerce an value to a particular type.
try_coerce	Coerce data container to the data type, raises a ~pan-
	dera.errors.ParserError if the coercion fails
call	Coerce data container to the data type.

7.15.2.1.3.1 pandera.dtypes.Timestamp.__init__

Timestamp.__init__()

7.15.2.1.3.2 pandera.dtypes.Timestamp.check

Timestamp.check(pandera_dtype)

Check that pandera *DataType* are equivalent.

Return type bool

7.15.2.1.3.3 pandera.dtypes.Timestamp.coerce

Timestamp.coerce(data_container)

Coerce data container to the data type.

7.15.2.1.3.4 pandera.dtypes.Timestamp.coerce_value

Timestamp.coerce_value(value)

Coerce an value to a particular type.

7.15.2.1.3.5 pandera.dtypes.Timestamp.try_coerce

Timestamp.try_coerce(data_container)

Coerce data container to the data type, raises a ~pandera.errors.ParserError if the coercion fails

Raises ParserError: if coercion fails

7.15.2.1.3.6 pandera.dtypes.Timestamp.__call__

Timestamp.__call__(data_container)

Coerce data container to the data type.

7.15.2.1.4 pandera.dtypes.DateTime

 ${\tt pandera.dtypes.} \textbf{\textit{DateTime}}$

alias of pandera.dtypes.Timestamp

7.15.2.1.5 pandera.dtypes.Timedelta

class pandera.dtypes.Timedelta

Semantic representation of a delta time data type.

Attributes

continuous	Whether the number data type is continuous.

Methods

init	
check	Check that pandera <i>DataType</i> are equivalent.
coerce	Coerce data container to the data type.
coerce_value	Coerce an value to a particular type.
try_coerce	Coerce data container to the data type, raises a ~pan-
	dera.errors.ParserError if the coercion fails
call	Coerce data container to the data type.

7.15.2.1.5.1 pandera.dtypes.Timedelta.__init__

Timedelta.__init__()

7.15.2.1.5.2 pandera.dtypes.Timedelta.check

Timedelta.check(pandera_dtype)

Check that pandera *DataType* are equivalent.

Return type bool

7.15.2.1.5.3 pandera.dtypes.Timedelta.coerce

Timedelta.coerce(data_container)

Coerce data container to the data type.

7.15.2.1.5.4 pandera.dtypes.Timedelta.coerce_value

Timedelta.coerce_value(value)

Coerce an value to a particular type.

7.15.2.1.5.5 pandera.dtypes.Timedelta.try_coerce

Timedelta.try_coerce(data_container)

Coerce data container to the data type, raises a ~pandera.errors.ParserError if the coercion fails

Raises ParserError: if coercion fails

7.15.2.1.5.6 pandera.dtypes.Timedelta.__call__

Timedelta.__call__(data_container)

Coerce data container to the data type.

7.15.2.1.6 pandera.dtypes.Category

class pandera.dtypes.Category(categories=None, ordered=False)

Semantic representation of a categorical data type.

Attributes

categories	
continuous	Whether the number data type is continuous.
ordered	

Methods

init	
check	Check that pandera DataType are equivalent.
coerce	Coerce data container to the data type.
coerce_value	Coerce an value to a particular type.
try_coerce	Coerce data container to the data type, raises a ~pan-
	dera.errors.ParserError if the coercion fails
call	Coerce data container to the data type.

7.15.2.1.6.1 pandera.dtypes.Category. init

Category.__init__(categories=None, ordered=False)

7.15.2.1.6.2 pandera.dtypes.Category.check

Category.check(pandera_dtype)

Check that pandera *DataType* are equivalent.

Return type bool

7.15.2.1.6.3 pandera.dtypes.Category.coerce

Category.coerce(data_container)

Coerce data container to the data type.

7.15.2.1.6.4 pandera.dtypes.Category.coerce_value

Category.coerce_value(value)

Coerce an value to a particular type.

7.15.2.1.6.5 pandera.dtypes.Category.try_coerce

 ${\tt Category.try_coerce}(\textit{data_container})$

Coerce data container to the data type, raises a ~pandera.errors.ParserError if the coercion fails

Raises ParserError: if coercion fails

7.15.2.1.6.6 pandera.dtypes.Category.__call__

Category.__call__(data_container)

Coerce data container to the data type.

7.15.2.1.7 pandera.dtypes.Float

class pandera.dtypes.Float

Semantic representation of a floating data type.

Attributes

bit_width	Number of bits used by the machine representation.
continuous	Whether the number data type is continuous.
exact	Whether the data type is an exact representation of a
	number.

Methods

Check that pandera <i>DataType</i> are equivalent.
Coerce data container to the data type.
Coerce an value to a particular type.
Coerce data container to the data type, raises a ~pan-
dera.errors.ParserError if the coercion fails
Coerce data container to the data type.

7.15.2.1.7.1 pandera.dtypes.Float.__init__

Float.__init__()

7.15.2.1.7.2 pandera.dtypes.Float.check

Float.check(pandera_dtype)

Check that pandera <code>DataType</code> are equivalent.

Return type bool

7.15.2.1.7.3 pandera.dtypes.Float.coerce

Float.coerce(data_container)

Coerce data container to the data type.

7.15.2.1.7.4 pandera.dtypes.Float.coerce_value

Float.coerce_value(value)

Coerce an value to a particular type.

7.15.2.1.7.5 pandera.dtypes.Float.try_coerce

Float.try_coerce(data_container)

Coerce data container to the data type, raises a ~pandera.errors.ParserError if the coercion fails

Raises ParserError: if coercion fails

7.15.2.1.7.6 pandera.dtypes.Float.__call__

Float.__call__(data_container)

Coerce data container to the data type.

7.15.2.1.8 pandera.dtypes.Float16

class pandera.dtypes.Float16

Semantic representation of a floating data type stored in 16 bits.

Attributes

bit_width	Number of bits used by the machine representation.
continuous	Whether the number data type is continuous.
exact	Whether the data type is an exact representation of a
	number.

Methods

init	
check	Check that pandera <i>DataType</i> are equivalent.
coerce	Coerce data container to the data type.
coerce_value	Coerce an value to a particular type.
try_coerce	Coerce data container to the data type, raises a ~pan-
	dera.errors.ParserError if the coercion fails
call	Coerce data container to the data type.

7.15.2.1.8.1 pandera.dtypes.Float16.__init__

Float16.__init__()

7.15.2.1.8.2 pandera.dtypes.Float16.check

Float16.check(pandera_dtype)

Check that pandera *DataType* are equivalent.

Return type bool

7.15.2.1.8.3 pandera.dtypes.Float16.coerce

Float16.coerce(data_container)

Coerce data container to the data type.

7.15.2.1.8.4 pandera.dtypes.Float16.coerce_value

Float16.coerce_value(value)

Coerce an value to a particular type.

7.15.2.1.8.5 pandera.dtypes.Float16.try_coerce

Float16.try_coerce(data_container)

Coerce data container to the data type, raises a ~pandera.errors.ParserError if the coercion fails

Raises ParserError: if coercion fails

7.15.2.1.8.6 pandera.dtypes.Float16.__call__

Float16.__call__(data_container)

Coerce data container to the data type.

7.15.2.1.9 pandera.dtypes.Float32

class pandera.dtypes.Float32

Semantic representation of a floating data type stored in 32 bits.

Attributes

bit_width	Number of bits used by the machine representation.
continuous	Whether the number data type is continuous.
exact	Whether the data type is an exact representation of a
	number.

Methods

init	
check	Check that pandera <i>DataType</i> are equivalent.
coerce	Coerce data container to the data type.
coerce_value	Coerce an value to a particular type.
try_coerce	Coerce data container to the data type, raises a ~pan-
	dera.errors.ParserError if the coercion fails
call	Coerce data container to the data type.

7.15.2.1.9.1 pandera.dtypes.Float32.__init__

Float32.__init__()

7.15.2.1.9.2 pandera.dtypes.Float32.check

Float32.check(pandera_dtype)

Check that pandera *DataType* are equivalent.

Return type bool

7.15.2.1.9.3 pandera.dtypes.Float32.coerce

Float32.coerce(data_container)

Coerce data container to the data type.

7.15.2.1.9.4 pandera.dtypes.Float32.coerce_value

Float32.coerce_value(value)

Coerce an value to a particular type.

7.15.2.1.9.5 pandera.dtypes.Float32.try_coerce

Float32.try_coerce(data_container)

Coerce data container to the data type, raises a ~pandera.errors.ParserError if the coercion fails

Raises ParserError: if coercion fails

7.15.2.1.9.6 pandera.dtypes.Float32.__call__

Float32.__call__(data_container)

Coerce data container to the data type.

7.15.2.1.10 pandera.dtypes.Float64

class pandera.dtypes.Float64

Semantic representation of a floating data type stored in 64 bits.

Attributes

bit_width	Number of bits used by the machine representation.
continuous	Whether the number data type is continuous.
exact	Whether the data type is an exact representation of a
	number.

Methods

init	
check	Check that pandera <i>DataType</i> are equivalent.
coerce	Coerce data container to the data type.
coerce_value	Coerce an value to a particular type.
try_coerce	Coerce data container to the data type, raises a ~pan- dera.errors.ParserError if the coercion fails
call	Coerce data container to the data type.

7.15.2.1.10.1 pandera.dtypes.Float64.__init__

Float64.__init__()

7.15.2.1.10.2 pandera.dtypes.Float64.check

Float64.check(pandera_dtype)

Check that pandera <code>DataType</code> are equivalent.

Return type bool

7.15.2.1.10.3 pandera.dtypes.Float64.coerce

Float64.coerce(data_container)

Coerce data container to the data type.

7.15.2.1.10.4 pandera.dtypes.Float64.coerce_value

Float64.coerce_value(value)

Coerce an value to a particular type.

7.15.2.1.10.5 pandera.dtypes.Float64.try_coerce

Float64.try_coerce(data_container)

Coerce data container to the data type, raises a ~pandera.errors.ParserError if the coercion fails

Raises ParserError: if coercion fails

7.15.2.1.10.6 pandera.dtypes.Float64.__call__

Float64.__call__(data_container)

Coerce data container to the data type.

7.15.2.1.11 pandera.dtypes.Float128

class pandera.dtypes.Float128

Semantic representation of a floating data type stored in 128 bits.

Attributes

bit_width	Number of bits used by the machine representation.
continuous	Whether the number data type is continuous.
exact	Whether the data type is an exact representation of a
	number.

Methods

init	
check	Check that pandera <i>DataType</i> are equivalent.
coerce	Coerce data container to the data type.
coerce_value	Coerce an value to a particular type.
try_coerce	Coerce data container to the data type, raises a ~pan-
	dera.errors.ParserError if the coercion fails
call	Coerce data container to the data type.

7.15.2.1.11.1 pandera.dtypes.Float128. init

Float128.__**init**__()

7.15.2.1.11.2 pandera.dtypes.Float128.check

Float128.check(pandera_dtype)

Check that pandera *DataType* are equivalent.

Return type bool

7.15.2.1.11.3 pandera.dtypes.Float128.coerce

Float128.coerce(data_container)

Coerce data container to the data type.

7.15.2.1.11.4 pandera.dtypes.Float128.coerce_value

Float128.coerce_value(value)

Coerce an value to a particular type.

7.15.2.1.11.5 pandera.dtypes.Float128.try_coerce

${\tt Float128.try_coerce}(\textit{data_container})$

Coerce data container to the data type, raises a ~pandera.errors.ParserError if the coercion fails

Raises ParserError: if coercion fails

7.15.2.1.11.6 pandera.dtypes.Float128.__call__

Float128.__call__(data_container)

Coerce data container to the data type.

7.15.2.1.12 pandera.dtypes.Int

class pandera.dtypes.Int

Semantic representation of an integer data type.

Attributes

bit_width	Number of bits used by the machine representation.
continuous	Whether the number data type is continuous.
exact	Whether the data type is an exact representation of a
	number.
signed	Whether the integer data type is signed.

Methods

init	
check	Check that pandera <i>DataType</i> are equivalent.
coerce	Coerce data container to the data type.
coerce_value	Coerce an value to a particular type.
try_coerce	Coerce data container to the data type, raises a ~pan-
	dera.errors.ParserError if the coercion fails
call	Coerce data container to the data type.

7.15.2.1.12.1 pandera.dtypes.Int.__init__

Int.__init__()

7.15.2.1.12.2 pandera.dtypes.Int.check

Int.check(pandera_dtype)

Check that pandera <code>DataType</code> are equivalent.

Return type bool

7.15.2.1.12.3 pandera.dtypes.Int.coerce

Int.coerce(data_container)

Coerce data container to the data type.

7.15.2.1.12.4 pandera.dtypes.Int.coerce_value

Int.coerce_value(value)

Coerce an value to a particular type.

7.15.2.1.12.5 pandera.dtypes.Int.try_coerce

Int.try_coerce(data_container)

Coerce data container to the data type, raises a ~pandera.errors.ParserError if the coercion fails

Raises ParserError: if coercion fails

7.15.2.1.12.6 pandera.dtypes.Int.__call__

Coerce data container to the data type.

7.15.2.1.13 pandera.dtypes.Int8

class pandera.dtypes.Int8

Semantic representation of an integer data type stored in 8 bits.

Attributes

bit_width	Number of bits used by the machine representation.
continuous	Whether the number data type is continuous.
exact	Whether the data type is an exact representation of a
	number.
signed	Whether the integer data type is signed.

Methods

init	
check	Check that pandera <i>DataType</i> are equivalent.
coerce	Coerce data container to the data type.
coerce_value	Coerce an value to a particular type.
try_coerce	Coerce data container to the data type, raises a ~pan- dera.errors.ParserError if the coercion fails
call	Coerce data container to the data type.

7.15.2.1.13.1 pandera.dtypes.Int8.__init__

Int8.__init__()

7.15.2.1.13.2 pandera.dtypes.Int8.check

Int8.check(pandera_dtype)

Check that pandera *DataType* are equivalent.

Return type bool

7.15.2.1.13.3 pandera.dtypes.Int8.coerce

Int8.coerce(data_container)

Coerce data container to the data type.

7.15.2.1.13.4 pandera.dtypes.Int8.coerce_value

Int8.coerce_value(value)

Coerce an value to a particular type.

7.15.2.1.13.5 pandera.dtypes.Int8.try_coerce

Int8.try_coerce(data_container)

Coerce data container to the data type, raises a ~pandera.errors.ParserError if the coercion fails

Raises ParserError: if coercion fails

7.15.2.1.13.6 pandera.dtypes.lnt8.__call__

Int8.__call__(data_container)

Coerce data container to the data type.

7.15.2.1.14 pandera.dtypes.Int16

class pandera.dtypes.Int16

Semantic representation of an integer data type stored in 16 bits.

Attributes

bit_width	Number of bits used by the machine representation.
continuous	Whether the number data type is continuous.
exact	Whether the data type is an exact representation of a
	number.
signed	Whether the integer data type is signed.

Methods

init	
check	Check that pandera <i>DataType</i> are equivalent.
coerce	Coerce data container to the data type.
coerce_value	Coerce an value to a particular type.
try_coerce	Coerce data container to the data type, raises a ~pan-dera.errors.ParserError if the coercion fails
call	Coerce data container to the data type.

7.15.2.1.14.1 pandera.dtypes.Int16.__init__

Int16.__init__()

7.15.2.1.14.2 pandera.dtypes.Int16.check

Int16.check(pandera_dtype)

Check that pandera *DataType* are equivalent.

Return type bool

7.15.2.1.14.3 pandera.dtypes.Int16.coerce

Int16.coerce(data_container)

Coerce data container to the data type.

7.15.2.1.14.4 pandera.dtypes.Int16.coerce_value

Int16.coerce_value(value)

Coerce an value to a particular type.

7.15.2.1.14.5 pandera.dtypes.Int16.try_coerce

Int16.try_coerce(data_container)

Coerce data container to the data type, raises a ~pandera.errors.ParserError if the coercion fails

Raises ParserError: if coercion fails

7.15.2.1.14.6 pandera.dtypes.Int16.__call__

Int16.__call__(data_container)

Coerce data container to the data type.

7.15.2.1.15 pandera.dtypes.Int32

class pandera.dtypes.Int32

Semantic representation of an integer data type stored in 32 bits.

Attributes

bit_width	Number of bits used by the machine representation.
continuous	Whether the number data type is continuous.
exact	Whether the data type is an exact representation of a
	number.
signed	Whether the integer data type is signed.

Methods

init	
check	Check that pandera <i>DataType</i> are equivalent.
coerce	Coerce data container to the data type.
coerce_value	Coerce an value to a particular type.
try_coerce	Coerce data container to the data type, raises a ~pan- dera.errors.ParserError if the coercion fails
call	Coerce data container to the data type.

7.15.2.1.15.1 pandera.dtypes.Int32.__init__

Int32.__init__()

7.15.2.1.15.2 pandera.dtypes.Int32.check

Int32.check(pandera_dtype)

Check that pandera DataType are equivalent.

Return type bool

7.15.2.1.15.3 pandera.dtypes.Int32.coerce

Int32.coerce(data_container)

Coerce data container to the data type.

7.15.2.1.15.4 pandera.dtypes.Int32.coerce_value

Int32.coerce_value(value)

Coerce an value to a particular type.

7.15.2.1.15.5 pandera.dtypes.Int32.try_coerce

Int32.try_coerce(data_container)

Coerce data container to the data type, raises a ~pandera.errors.ParserError if the coercion fails

Raises ParserError: if coercion fails

7.15.2.1.15.6 pandera.dtypes.Int32.__call__

Int32.__call__(data_container)

Coerce data container to the data type.

7.15.2.1.16 pandera.dtypes.Int64

class pandera.dtypes.Int64

Semantic representation of an integer data type stored in 64 bits.

Attributes

bit_width	Number of bits used by the machine representation.
continuous	Whether the number data type is continuous.
exact	Whether the data type is an exact representation of a
	number.
signed	Whether the integer data type is signed.

Methods

init	
check	Check that pandera <i>DataType</i> are equivalent.
coerce	Coerce data container to the data type.
coerce_value	Coerce an value to a particular type.
try_coerce	Coerce data container to the data type, raises a ~pan-
	dera.errors.ParserError if the coercion fails
call	Coerce data container to the data type.

7.15.2.1.16.1 pandera.dtypes.Int64. init

Int64.__init__()

7.15.2.1.16.2 pandera.dtypes.Int64.check

Int64.check(pandera_dtype)

Check that pandera *DataType* are equivalent.

Return type bool

7.15.2.1.16.3 pandera.dtypes.Int64.coerce

Int64.coerce(data_container)

Coerce data container to the data type.

7.15.2.1.16.4 pandera.dtypes.Int64.coerce_value

Int64.coerce_value(value)

Coerce an value to a particular type.

7.15.2.1.16.5 pandera.dtypes.Int64.try_coerce

Int64.try_coerce(data_container)

Coerce data container to the data type, raises a ~pandera.errors.ParserError if the coercion fails

Raises ParserError: if coercion fails

7.15.2.1.16.6 pandera.dtypes.Int64.__call__

```
Int64.__call__(data_container)
```

Coerce data container to the data type.

7.15.2.1.17 pandera.dtypes.UInt

class pandera.dtypes.UInt

Semantic representation of an unsigned integer data type.

Attributes

bit_width	Number of bits used by the machine representation.
continuous	Whether the number data type is continuous.
exact	Whether the data type is an exact representation of a
	number.
signed	Whether the integer data type is signed.

Methods

init	
check	Check that pandera <i>DataType</i> are equivalent.
coerce	Coerce data container to the data type.
coerce_value	Coerce an value to a particular type.
try_coerce	Coerce data container to the data type, raises a ~pan-
	dera.errors.ParserError if the coercion fails
call	Coerce data container to the data type.

7.15.2.1.17.1 pandera.dtypes.UInt.__init__

UInt.__init__()

7.15.2.1.17.2 pandera.dtypes.UInt.check

UInt.check(pandera_dtype)

Check that pandera <code>DataType</code> are equivalent.

Return type bool

7.15.2.1.17.3 pandera.dtypes.UInt.coerce

UInt.coerce(data_container)

Coerce data container to the data type.

7.15.2.1.17.4 pandera.dtypes.UInt.coerce_value

UInt.coerce_value(value)

Coerce an value to a particular type.

7.15.2.1.17.5 pandera.dtypes.UInt.try_coerce

UInt.try_coerce(data_container)

Coerce data container to the data type, raises a ~pandera.errors.ParserError if the coercion fails

Raises ParserError: if coercion fails

7.15.2.1.17.6 pandera.dtypes.UInt.__call__

UInt.__call__(data_container)

Coerce data container to the data type.

7.15.2.1.18 pandera.dtypes.UInt8

class pandera.dtypes.UInt8

Semantic representation of an unsigned integer data type stored in 8 bits.

Attributes

bit_width	Number of bits used by the machine representation.
continuous	Whether the number data type is continuous.
exact	Whether the data type is an exact representation of a
	number.
signed	Whether the integer data type is signed.

Methods

init	
check	Check that pandera <i>DataType</i> are equivalent.
coerce	Coerce data container to the data type.
coerce_value	Coerce an value to a particular type.
try_coerce	Coerce data container to the data type, raises a ~pan-dera.errors.ParserError if the coercion fails
call	Coerce data container to the data type.

7.15.2.1.18.1 pandera.dtypes.UInt8.__init__

UInt8.__init__()

7.15.2.1.18.2 pandera.dtypes.UInt8.check

UInt8.check(pandera_dtype)

Check that pandera *DataType* are equivalent.

Return type bool

7.15.2.1.18.3 pandera.dtypes.UInt8.coerce

UInt8.coerce(data_container)

Coerce data container to the data type.

7.15.2.1.18.4 pandera.dtypes.UInt8.coerce_value

UInt8.coerce_value(value)

Coerce an value to a particular type.

7.15.2.1.18.5 pandera.dtypes.UInt8.try_coerce

UInt8.try_coerce(data_container)

Coerce data container to the data type, raises a ~pandera.errors.ParserError if the coercion fails

Raises ParserError: if coercion fails

7.15.2.1.18.6 pandera.dtypes.UInt8.__call__

UInt8.__call__(data_container)

Coerce data container to the data type.

7.15.2.1.19 pandera.dtypes.UInt16

class pandera.dtypes.UInt16

Semantic representation of an unsigned integer data type stored in 16 bits.

Attributes

bit_width	Number of bits used by the machine representation.
continuous	Whether the number data type is continuous.
exact	Whether the data type is an exact representation of a
	number.
signed	Whether the integer data type is signed.

Methods

init	
check	Check that pandera <i>DataType</i> are equivalent.
	<u> </u>
coerce	Coerce data container to the data type.
coerce_value	Coerce an value to a particular type.
try_coerce	Coerce data container to the data type, raises a ~pan-
	dera.errors.ParserError if the coercion fails
call	Coerce data container to the data type.

7.15.2.1.19.1 pandera.dtypes.UInt16.__init__

UInt16.__init__()

7.15.2.1.19.2 pandera.dtypes.UInt16.check

UInt16.check(pandera_dtype)

Check that pandera *DataType* are equivalent.

Return type bool

7.15.2.1.19.3 pandera.dtypes.UInt16.coerce

UInt16.coerce(data_container)

Coerce data container to the data type.

7.15.2.1.19.4 pandera.dtypes.UInt16.coerce_value

UInt16.coerce_value(value)

Coerce an value to a particular type.

7.15.2.1.19.5 pandera.dtypes.UInt16.try_coerce

UInt16.try_coerce(data_container)

Coerce data container to the data type, raises a ~pandera.errors.ParserError if the coercion fails

Raises ParserError: if coercion fails

7.15.2.1.19.6 pandera.dtypes.UInt16.__call__

UInt16.__call__(data_container)

Coerce data container to the data type.

7.15.2.1.20 pandera.dtypes.UInt32

class pandera.dtypes.UInt32

Semantic representation of an unsigned integer data type stored in 32 bits.

Attributes

bit_width	Number of bits used by the machine representation.
continuous	Whether the number data type is continuous.
exact	Whether the data type is an exact representation of a
	number.
signed	Whether the integer data type is signed.

Methods

Check that pandera <i>DataType</i> are equivalent.
Coerce data container to the data type.
Coerce an value to a particular type.
Coerce data container to the data type, raises a ~pan-
dera.errors.ParserError if the coercion fails
Coerce data container to the data type.

7.15.2.1.20.1 pandera.dtypes.UInt32.__init__

UInt32.__init__()

7.15.2.1.20.2 pandera.dtypes.UInt32.check

UInt32.check(pandera_dtype)

Check that pandera *DataType* are equivalent.

Return type bool

7.15.2.1.20.3 pandera.dtypes.UInt32.coerce

UInt32.coerce(data_container)

Coerce data container to the data type.

7.15.2.1.20.4 pandera.dtypes.UInt32.coerce_value

UInt32.coerce_value(value)

Coerce an value to a particular type.

7.15.2.1.20.5 pandera.dtypes.UInt32.try_coerce

UInt32.try_coerce(data_container)

Coerce data container to the data type, raises a ~pandera.errors.ParserError if the coercion fails

Raises ParserError: if coercion fails

7.15.2.1.20.6 pandera.dtypes.UInt32.__call__

UInt32.__call__(data_container)

Coerce data container to the data type.

7.15.2.1.21 pandera.dtypes.UInt64

class pandera.dtypes.UInt64

Semantic representation of an unsigned integer data type stored in 64 bits.

Attributes

bit_width	Number of bits used by the machine representation.
continuous	Whether the number data type is continuous.
exact	Whether the data type is an exact representation of a
	number.
signed	Whether the integer data type is signed.

Methods

Check that pandera DataType are equivalent.
Coerce data container to the data type.
Coerce an value to a particular type.
Coerce data container to the data type, raises a ~pan-
dera.errors.ParserError if the coercion fails
Coerce data container to the data type.

7.15.2.1.21.1 pandera.dtypes.UInt64. init

UInt64.__init__()

7.15.2.1.21.2 pandera.dtypes.UInt64.check

UInt64.check(pandera_dtype)

Check that pandera *DataType* are equivalent.

Return type bool

7.15.2.1.21.3 pandera.dtypes.UInt64.coerce

UInt64.coerce(data_container)

Coerce data container to the data type.

7.15.2.1.21.4 pandera.dtypes.UInt64.coerce_value

UInt64.coerce_value(value)

Coerce an value to a particular type.

7.15.2.1.21.5 pandera.dtypes.UInt64.try_coerce

UInt64.try_coerce(data_container)

Coerce data container to the data type, raises a ~pandera.errors.ParserError if the coercion fails

Raises ParserError: if coercion fails

7.15.2.1.21.6 pandera.dtypes.UInt64.__call__

```
UInt64.__call__(data_container)
```

Coerce data container to the data type.

7.15.2.1.22 pandera.dtypes.Complex

class pandera.dtypes.Complex

Semantic representation of a complex number data type.

bit_width	Number of bits used by the machine representation.
continuous	Whether the number data type is continuous.
exact	Whether the data type is an exact representation of a
	number.

Methods

init	
check	Check that pandera <i>DataType</i> are equivalent.
coerce	Coerce data container to the data type.
coerce_value	Coerce an value to a particular type.
try_coerce	Coerce data container to the data type, raises a ~pan-
	dera.errors.ParserError if the coercion fails
call	Coerce data container to the data type.

7.15.2.1.22.1 pandera.dtypes.Complex.__init__

Complex.__init__()

7.15.2.1.22.2 pandera.dtypes.Complex.check

Complex.check(pandera_dtype)

Check that pandera *DataType* are equivalent.

Return type bool

7.15.2.1.22.3 pandera.dtypes.Complex.coerce

Complex.coerce(data_container)

Coerce data container to the data type.

7.15.2.1.22.4 pandera.dtypes.Complex.coerce_value

Complex.coerce_value(value)

Coerce an value to a particular type.

7.15.2.1.22.5 pandera.dtypes.Complex.try coerce

Complex.try_coerce(data_container)

Coerce data container to the data type, raises a ~pandera.errors.ParserError if the coercion fails

Raises ParserError: if coercion fails

7.15.2.1.22.6 pandera.dtypes.Complex.__call__

Complex.__call__(data_container)

Coerce data container to the data type.

7.15.2.1.23 pandera.dtypes.Complex64

class pandera.dtypes.Complex64

Semantic representation of a complex number data type stored in 64 bits.

Attributes

bit_width	Number of bits used by the machine representation.
continuous	Whether the number data type is continuous.
exact	Whether the data type is an exact representation of a
	number.

Methods

init	
check	Check that pandera <i>DataType</i> are equivalent.
coerce	Coerce data container to the data type.
coerce_value	Coerce an value to a particular type.
try_coerce	Coerce data container to the data type, raises a ~pan-
	dera.errors.ParserError if the coercion fails
call	Coerce data container to the data type.

7.15.2.1.23.1 pandera.dtypes.Complex64.__init__

Complex64.__init__()

7.15.2.1.23.2 pandera.dtypes.Complex64.check

Complex64.check(pandera_dtype)

Check that pandera *DataType* are equivalent.

Return type bool

7.15.2.1.23.3 pandera.dtypes.Complex64.coerce

Complex64.coerce(data_container)

Coerce data container to the data type.

7.15.2.1.23.4 pandera.dtypes.Complex64.coerce_value

Complex64.coerce_value(value)

Coerce an value to a particular type.

7.15.2.1.23.5 pandera.dtypes.Complex64.try_coerce

Complex64.try_coerce(data_container)

Coerce data container to the data type, raises a ~pandera.errors.ParserError if the coercion fails

Raises ParserError: if coercion fails

7.15.2.1.23.6 pandera.dtypes.Complex64.__call__

Complex64.__call__(data_container)

Coerce data container to the data type.

7.15.2.1.24 pandera.dtypes.Complex128

class pandera.dtypes.Complex128

Semantic representation of a complex number data type stored in 128 bits.

Attributes

bit_width	Number of bits used by the machine representation.
continuous	Whether the number data type is continuous.
exact	Whether the data type is an exact representation of a
	number.

Methods

init	
check	Check that pandera <i>DataType</i> are equivalent.
coerce	Coerce data container to the data type.
coerce_value	Coerce an value to a particular type.
try_coerce	Coerce data container to the data type, raises a ~pan-
	dera.errors.ParserError if the coercion fails
call	Coerce data container to the data type.

7.15.2.1.24.1 pandera.dtypes.Complex128.__init__

Complex128.__init__()

7.15.2.1.24.2 pandera.dtypes.Complex128.check

Complex128.check(pandera_dtype)

Check that pandera *DataType* are equivalent.

Return type bool

7.15.2.1.24.3 pandera.dtypes.Complex128.coerce

Complex128.coerce(data_container)

Coerce data container to the data type.

7.15.2.1.24.4 pandera.dtypes.Complex128.coerce_value

Complex128.coerce_value(value)

Coerce an value to a particular type.

7.15.2.1.24.5 pandera.dtypes.Complex128.try_coerce

Complex128.try_coerce(data_container)

Coerce data container to the data type, raises a ~pandera.errors.ParserError if the coercion fails

Raises ParserError: if coercion fails

7.15.2.1.24.6 pandera.dtypes.Complex128.__call__

Complex128.__call__(data_container)

Coerce data container to the data type.

7.15.2.1.25 pandera.dtypes.Complex256

class pandera.dtypes.Complex256

Semantic representation of a complex number data type stored in 256 bits.

Attributes

bit_width	Number of bits used by the machine representation.
continuous	Whether the number data type is continuous.
exact	Whether the data type is an exact representation of a
	number.

Methods

init	
check	Check that pandera DataType are equivalent.
coerce	Coerce data container to the data type.
coerce_value	Coerce an value to a particular type.
try_coerce	Coerce data container to the data type, raises a ~pan-
	dera.errors.ParserError if the coercion fails
call	Coerce data container to the data type.

7.15.2.1.25.1 pandera.dtypes.Complex256.__init__

Complex256.__init__()

7.15.2.1.25.2 pandera.dtypes.Complex256.check

 ${\tt Complex256.check}(pandera_dtype)$

Check that pandera <code>DataType</code> are equivalent.

Return type bool

7.15.2.1.25.3 pandera.dtypes.Complex256.coerce

Complex256.coerce(data_container)

Coerce data container to the data type.

7.15.2.1.25.4 pandera.dtypes.Complex256.coerce_value

Complex256.coerce_value(value)

Coerce an value to a particular type.

7.15.2.1.25.5 pandera.dtypes.Complex256.try_coerce

Complex256.try_coerce(data_container)

Coerce data container to the data type, raises a ~pandera.errors.ParserError if the coercion fails

Raises ParserError: if coercion fails

7.15.2.1.25.6 pandera.dtypes.Complex256.__call__

Complex256.__call__(data_container)

Coerce data container to the data type.

7.15.2.1.26 pandera.dtypes.String

class pandera.dtypes.String

Semantic representation of a string data type.

Attributes

continuous	Whether the number data type is continuous.

Methods

init	
check	Check that pandera <i>DataType</i> are equivalent.
coerce	Coerce data container to the data type.
coerce_value	Coerce an value to a particular type.
try_coerce	Coerce data container to the data type, raises a ~pan-
	dera.errors.ParserError if the coercion fails
call	Coerce data container to the data type.

7.15.2.1.26.1 pandera.dtypes.String. init

String.__init__()

7.15.2.1.26.2 pandera.dtypes.String.check

String.check(pandera_dtype)

Check that pandera *DataType* are equivalent.

Return type bool

7.15.2.1.26.3 pandera.dtypes.String.coerce

String.coerce(data_container)

Coerce data container to the data type.

7.15.2.1.26.4 pandera.dtypes.String.coerce_value

String.coerce_value(value)

Coerce an value to a particular type.

7.15.2.1.26.5 pandera.dtypes.String.try_coerce

String.try_coerce(data_container)

Coerce data container to the data type, raises a ~pandera.errors.ParserError if the coercion fails

Raises ParserError: if coercion fails

7.15.2.1.26.6 pandera.dtypes.String.__call__

String.__call__(data_container)

Coerce data container to the data type.

7.15.2.2 Pandas Dtypes

Listed here for compatibility with pandera versions < 0.7. Passing native pandas dtypes to pandera components is preferred.

pandera.engines.pandas_engine.BOOL	Semantic representation of a pandas.BooleanDtype.
pandera.engines.pandas_engine.INT8	Semantic representation of a pandas. Int8Dtype.
pandera.engines.pandas_engine.INT16	Semantic representation of a pandas. Int16Dtype.
pandera.engines.pandas_engine.INT32	Semantic representation of a pandas. Int32Dtype.
pandera.engines.pandas_engine.INT64	Semantic representation of a pandas. Int64Dtype.
pandera.engines.pandas_engine.UINT8	Semantic representation of a pandas.UInt8Dtype.
pandera.engines.pandas_engine.UINT16	Semantic representation of a pandas.UInt16Dtype.
pandera.engines.pandas_engine.UINT32	Semantic representation of a pandas.UInt32Dtype.
pandera.engines.pandas_engine.UINT64	Semantic representation of a pandas.UInt64Dtype.
pandera.engines.pandas_engine.STRING	Semantic representation of a pandas.StringDtype.
pandera.engines.numpy_engine.Object	Semantic representation of a numpy.object
pandera.engines.pandas_engine.DateTime	Semantic representation of a pandas.
	DatetimeTZDtype.

7.15.2.2.1 pandera.engines.pandas_engine.BOOL

class pandera.engines.pandas_engine.BOOL

Semantic representation of a pandas.BooleanDtype.

Attributes

continuous	Whether the number data type is continuous.
exact	Whether the data type is an exact representation of a
	number.
type	Native pandas dtype boxed by the data type.

Methods

init	
check	Check that pandera <i>DataType</i> are equivalent.
coerce	Pure coerce without catching exceptions.
coerce_value	Coerce an value to specified datatime type.
try_coerce	Coerce data container to the data type, raises a ~pan-dera.errors.ParserError if the coercion fails
cal1	Coerce data container to the data type.

7.15.2.2.1.1 pandera.engines.pandas_engine.BOOL.__init__

BOOL.__init__()

7.15.2.2.1.2 pandera.engines.pandas engine.BOOL.check

BOOL.check(pandera_dtype)

Check that pandera *DataType* are equivalent.

Return type bool

7.15.2.2.1.3 pandera.engines.pandas engine.BOOL.coerce

BOOL.coerce(data_container)

Pure coerce without catching exceptions.

Return type Union[Series, Index, DataFrame]

7.15.2.2.1.4 pandera.engines.pandas_engine.BOOL.coerce_value

BOOL.coerce_value(value)

Coerce an value to specified datatime type.

Return type Any

7.15.2.2.1.5 pandera.engines.pandas_engine.BOOL.try_coerce

BOOL.try_coerce(data_container)

Coerce data container to the data type, raises a ~pandera.errors.ParserError if the coercion fails

Raises ParserError: if coercion fails

Return type Union[Series, Index, DataFrame]

7.15.2.2.1.6 pandera.engines.pandas_engine.BOOL.__call__

```
BOOL.__call__(data_container)
```

Coerce data container to the data type.

7.15.2.2.2 pandera.engines.pandas_engine.INT8

class pandera.engines.pandas_engine.INT8

Semantic representation of a pandas. Int8Dtype.

bit_width	Number of bits used by the machine representation.
continuous	Whether the number data type is continuous.
exact	Whether the data type is an exact representation of a
	number.
signed	Whether the integer data type is signed.
type	Native pandas dtype boxed by the data type.

Methods

init	
check	Check that pandera <i>DataType</i> are equivalent.
coerce	Pure coerce without catching exceptions.
coerce_value	Coerce an value to a particular type.
try_coerce	Coerce data container to the data type, raises a ~pan-
	dera.errors.ParserError if the coercion fails
call	Coerce data container to the data type.

7.15.2.2.2.1 pandera.engines.pandas_engine.INT8.__init__

INT8.__init__()

7.15.2.2.2.2 pandera.engines.pandas_engine.INT8.check

INT8.check(pandera_dtype)

Check that pandera <code>DataType</code> are equivalent.

Return type bool

7.15.2.2.2.3 pandera.engines.pandas_engine.INT8.coerce

INT8.coerce(data_container)

Pure coerce without catching exceptions.

Return type Union[Series, Index, DataFrame]

7.15.2.2.2.4 pandera.engines.pandas engine.INT8.coerce value

INT8.coerce_value(value)

Coerce an value to a particular type.

Return type Any

7.15.2.2.2.5 pandera.engines.pandas engine.INT8.try coerce

INT8.try_coerce(data_container)

Coerce data container to the data type, raises a ~pandera.errors.ParserError if the coercion fails

Raises ParserError: if coercion fails

Return type Union[Series, Index, DataFrame]

7.15.2.2.2.6 pandera.engines.pandas_engine.INT8.__call__

INT8.__call__(data_container)

Coerce data container to the data type.

7.15.2.2.3 pandera.engines.pandas_engine.INT16

class pandera.engines.pandas_engine.INT16

Semantic representation of a pandas. Int16Dtype.

Attributes

bit_width	Number of bits used by the machine representation.
continuous	Whether the number data type is continuous.
exact	Whether the data type is an exact representation of a
	number.
signed	Whether the integer data type is signed.
type	Native pandas dtype boxed by the data type.

Methods

init	
check	Check that pandera <i>DataType</i> are equivalent.
coerce	Pure coerce without catching exceptions.
coerce_value	Coerce an value to a particular type.
try_coerce	Coerce data container to the data type, raises a ~pan-dera.errors.ParserError if the coercion fails
call	Coerce data container to the data type.

7.15.2.2.3.1 pandera.engines.pandas engine.INT16. init INT16.__init__() 7.15.2.2.3.2 pandera.engines.pandas_engine.INT16.check INT16.check(pandera_dtype) Check that pandera *DataType* are equivalent. Return type bool 7.15.2.2.3.3 pandera.engines.pandas engine.INT16.coerce INT16.coerce(data_container) Pure coerce without catching exceptions. **Return type** Union[Series, Index, DataFrame] 7.15.2.2.3.4 pandera.engines.pandas engine.INT16.coerce value INT16.coerce_value(value) Coerce an value to a particular type. Return type Any 7.15.2.2.3.5 pandera.engines.pandas engine.INT16.try coerce INT16.try_coerce(data_container) Coerce data container to the data type, raises a ~pandera.errors.ParserError if the coercion fails Raises ParserError: if coercion fails

7.15.2.2.3.6 pandera.engines.pandas engine.INT16. call

Return type Union[Series, Index, DataFrame]

```
INT16.__call__(data_container)
```

Coerce data container to the data type.

7.15.2.2.4 pandera.engines.pandas_engine.INT32

class pandera.engines.pandas_engine.INT32

 $Semantic\ representation\ of\ a\ pandas. Int {\tt 32Dtype}.$

bit_width	Number of bits used by the machine representation.
continuous	Whether the number data type is continuous.
exact	Whether the data type is an exact representation of a
	number.
signed	Whether the integer data type is signed.
type	Native pandas dtype boxed by the data type.

Methods

init	
check	Check that pandera <i>DataType</i> are equivalent.
coerce	Pure coerce without catching exceptions.
coerce_value	Coerce an value to a particular type.
try_coerce	Coerce data container to the data type, raises a ~pan-
	dera.errors.ParserError if the coercion fails
call	Coerce data container to the data type.

7.15.2.2.4.1 pandera.engines.pandas_engine.INT32.__init__

INT32.__init__()

7.15.2.2.4.2 pandera.engines.pandas_engine.INT32.check

INT32.check(pandera_dtype)

Check that pandera DataType are equivalent.

Return type bool

7.15.2.2.4.3 pandera.engines.pandas_engine.INT32.coerce

INT32.coerce(data_container)

Pure coerce without catching exceptions.

Return type Union[Series, Index, DataFrame]

7.15.2.2.4.4 pandera.engines.pandas engine.INT32.coerce value

INT32.coerce_value(value)

Coerce an value to a particular type.

Return type Any

7.15.2.2.4.5 pandera.engines.pandas engine.INT32.try coerce

INT32.try_coerce(data_container)

Coerce data container to the data type, raises a ~pandera.errors.ParserError if the coercion fails

Raises ParserError: if coercion fails

Return type Union[Series, Index, DataFrame]

7.15.2.2.4.6 pandera.engines.pandas_engine.INT32.__call__

INT32.__call__(data_container)

Coerce data container to the data type.

7.15.2.2.5 pandera.engines.pandas_engine.INT64

class pandera.engines.pandas_engine.INT64

Semantic representation of a pandas. Int64Dtype.

Attributes

bit_width	Number of bits used by the machine representation.
continuous	Whether the number data type is continuous.
exact	Whether the data type is an exact representation of a
	number.
signed	Whether the integer data type is signed.
type	Native pandas dtype boxed by the data type.

Methods

init	
check	Check that pandera <i>DataType</i> are equivalent.
coerce	Pure coerce without catching exceptions.
coerce_value	Coerce an value to a particular type.
try_coerce	Coerce data container to the data type, raises a ~pan-
	dera.errors.ParserError if the coercion fails
cal1	Coerce data container to the data type.

```
7.15.2.2.5.1 pandera.engines.pandas engine.INT64. init
     INT64.__init__()
     7.15.2.2.5.2 pandera.engines.pandas_engine.INT64.check
     INT64.check(pandera_dtype)
          Check that pandera DataType are equivalent.
              Return type bool
     7.15.2.2.5.3 pandera.engines.pandas engine.INT64.coerce
     INT64.coerce(data_container)
          Pure coerce without catching exceptions.
              Return type Union[Series, Index, DataFrame]
     7.15.2.2.5.4 pandera.engines.pandas_engine.INT64.coerce_value
     INT64.coerce_value(value)
          Coerce an value to a particular type.
              Return type Any
     7.15.2.2.5.5 pandera.engines.pandas engine.INT64.try coerce
     INT64.try_coerce(data_container)
          Coerce data container to the data type, raises a ~pandera.errors.ParserError if the coercion fails
              Raises ParserError: if coercion fails
              Return type Union[Series, Index, DataFrame]
     7.15.2.2.5.6 pandera.engines.pandas engine.INT64. call
     INT64.__call__(data_container)
          Coerce data container to the data type.
7.15.2.2.6 pandera.engines.pandas_engine.UINT8
```

class pandera.engines.pandas_engine.UINT8

Semantic representation of a pandas.UInt8Dtype.

bit_width	Number of bits used by the machine representation.
continuous	Whether the number data type is continuous.
exact	Whether the data type is an exact representation of a
	number.
signed	Whether the integer data type is signed.
type	Native pandas dtype boxed by the data type.

Methods

init	
check	Check that pandera <i>DataType</i> are equivalent.
coerce	Pure coerce without catching exceptions.
coerce_value	Coerce an value to a particular type.
try_coerce	Coerce data container to the data type, raises a ~pan-
	dera.errors.ParserError if the coercion fails
call	Coerce data container to the data type.

7.15.2.2.6.1 pandera.engines.pandas_engine.UINT8.__init__

UINT8.__init__()

7.15.2.2.6.2 pandera.engines.pandas_engine.UINT8.check

UINT8.check(pandera_dtype)

Check that pandera <code>DataType</code> are equivalent.

Return type bool

7.15.2.2.6.3 pandera.engines.pandas_engine.UINT8.coerce

UINT8.coerce(data_container)

Pure coerce without catching exceptions.

Return type Union[Series, Index, DataFrame]

7.15.2.2.6.4 pandera.engines.pandas engine.UINT8.coerce value

UINT8.coerce_value(value)

Coerce an value to a particular type.

Return type Any

7.15.2.2.6.5 pandera.engines.pandas_engine.UINT8.try_coerce

UINT8.try_coerce(data_container)

Coerce data container to the data type, raises a ~pandera.errors.ParserError if the coercion fails

Raises ParserError: if coercion fails

Return type Union[Series, Index, DataFrame]

7.15.2.2.6.6 pandera.engines.pandas_engine.UINT8.__call__

UINT8.__call__(data_container)

Coerce data container to the data type.

7.15.2.2.7 pandera.engines.pandas_engine.UINT16

class pandera.engines.pandas_engine.UINT16

Semantic representation of a pandas. UInt16Dtype.

Attributes

bit_width	Number of bits used by the machine representation.
continuous	Whether the number data type is continuous.
exact	Whether the data type is an exact representation of a
	number.
signed	Whether the integer data type is signed.
type	Native pandas dtype boxed by the data type.

Methods

init	
check	Check that pandera <i>DataType</i> are equivalent.
coerce	Pure coerce without catching exceptions.
coerce_value	Coerce an value to a particular type.
try_coerce	Coerce data container to the data type, raises a ~pan-
	dera.errors.ParserError if the coercion fails
call	Coerce data container to the data type.

UINT32.__init__()

7.15.2.2.8.2 pandera.engines.pandas_engine.UINT32.check

UINT32.check(pandera_dtype)

Check that pandera <code>DataType</code> are equivalent.

Return type bool

7.15.2.2.8.3 pandera.engines.pandas_engine.UINT32.coerce

UINT32.coerce(data_container)

Pure coerce without catching exceptions.

Return type Union[Series, Index, DataFrame]

7.15.2.2.8.4 pandera.engines.pandas engine.UINT32.coerce value

UINT32.coerce_value(value)

Coerce an value to a particular type.

Return type Any

7.15.2.2.8.5 pandera.engines.pandas engine.UINT32.try coerce

UINT32.try_coerce(data_container)

Coerce data container to the data type, raises a ~pandera.errors.ParserError if the coercion fails

Raises ParserError: if coercion fails

Return type Union[Series, Index, DataFrame]

7.15.2.2.8.6 pandera.engines.pandas_engine.UINT32.__call__

UINT32.__call__(data_container)

Coerce data container to the data type.

7.15.2.2.9 pandera.engines.pandas_engine.UINT64

class pandera.engines.pandas_engine.UINT64

Semantic representation of a pandas.UInt64Dtype.

Attributes

bit_width	Number of bits used by the machine representation.
continuous	Whether the number data type is continuous.
exact	Whether the data type is an exact representation of a
	number.
signed	Whether the integer data type is signed.
type	Native pandas dtype boxed by the data type.

Methods

init	
check	Charle that mandana Data Turna are againstant
спеск	Check that pandera <i>DataType</i> are equivalent.
coerce	Pure coerce without catching exceptions.
coerce_value	Coerce an value to a particular type.
try_coerce	Coerce data container to the data type, raises a ~pan-
	dera.errors.ParserError if the coercion fails
call	Coerce data container to the data type.

```

          Check that pandera DataType are equivalent.
              Return type bool
     7.15.2.2.9.3 pandera.engines.pandas engine.UINT64.coerce
     UINT64.coerce(data_container)
          Pure coerce without catching exceptions.
              Return type Union[Series, Index, DataFrame]
     7.15.2.2.9.4 pandera.engines.pandas_engine.UINT64.coerce_value
     UINT64.coerce_value(value)
          Coerce an value to a particular type.
              Return type Any
     7.15.2.2.9.5 pandera.engines.pandas engine.UINT64.try coerce
     UINT64.try_coerce(data_container)
          Coerce data container to the data type, raises a ~pandera.errors.ParserError if the coercion fails
              Raises ParserError: if coercion fails
              Return type Union[Series, Index, DataFrame]
     7.15.2.2.9.6 pandera.engines.pandas engine.UINT64. call
     UINT64.__call__(data_container)
          Coerce data container to the data type.
7.15.2.2.10 pandera.engines.pandas_engine.STRING
class pandera.engines.pandas_engine.STRING(storage='python')
     Semantic representation of a pandas. StringDtype.
```

continuous	Whether the number data type is continuous.
storage	
	Na La
type	Native pandas dtype boxed by the data type.

Methods

init	
check	Check that pandera <i>DataType</i> are equivalent.
coerce	Pure coerce without catching exceptions.
coerce_value	Coerce an value to a particular type.
from_parametrized_dtype	Convert a pandas.StringDtype to a Pandera
	<pre>pandera.engines.pandas_engine.STRING.</pre>
try_coerce	Coerce data container to the data type, raises a ~pan-
	dera.errors.ParserError if the coercion fails
call	Coerce data container to the data type.

7.15.2.2.10.1 pandera.engines.pandas_engine.STRING.__init__

STRING.__init__(storage='python')

7.15.2.2.10.2 pandera.engines.pandas_engine.STRING.check

STRING.check(pandera_dtype)

Check that pandera DataType are equivalent.

Return type bool

7.15.2.2.10.3 pandera.engines.pandas_engine.STRING.coerce

STRING.coerce(data_container)

Pure coerce without catching exceptions.

Return type Union[Series, Index, DataFrame]

7.15.2.2.10.4 pandera.engines.pandas engine.STRING.coerce value

STRING.coerce_value(value)

Coerce an value to a particular type.

Return type Any

7.15.2.2.10.5 pandera.engines.pandas engine.STRING.from parametrized dtype

classmethod STRING.from_parametrized_dtype(pd_dtype)

Convert a pandas. StringDtype to a Pandera pandera.engines.pandas_engine.STRING.

7.15.2.2.10.6 pandera.engines.pandas_engine.STRING.try_coerce

STRING.try_coerce(data_container)

Coerce data container to the data type, raises a ~pandera.errors.ParserError if the coercion fails

Raises ParserError: if coercion fails

Return type Union[Series, Index, DataFrame]

7.15.2.2.10.7 pandera.engines.pandas_engine.STRING.__call__

STRING.__call__(data_container)

Coerce data container to the data type.

7.15.2.2.11 pandera.engines.numpy_engine.Object

class pandera.engines.numpy_engine.Object

Semantic representation of a numpy.object_.

Attributes

continuous	Whether the number data type is continuous.
type	Native numpy dtype boxed by the data type.

Methods

Check that pandera DataType are equivalent.
Pure coerce without catching exceptions.
Coerce an value to a particular type.
Coerce data container to the data type, raises a ~pan-
dera.errors.ParserError if the coercion fails
Coerce data container to the data type.

```
7.15.2.2.11.1 pandera.engines.numpy engine.Object. init
     Object.__init__()
     7.15.2.2.11.2 pandera.engines.numpy_engine.Object.check
     Object.check(pandera_dtype)
          Check that pandera DataType are equivalent.
              Return type bool
     7.15.2.2.11.3 pandera.engines.numpy engine.Object.coerce
     Object.coerce(data_container)
          Pure coerce without catching exceptions.
              Return type Union[Series, Index, DataFrame]
     7.15.2.2.11.4 pandera.engines.numpy engine.Object.coerce value
     Object.coerce_value(value)
          Coerce an value to a particular type.
              Return type Any
     7.15.2.2.11.5 pandera.engines.numpy engine.Object.try coerce
     Object.try_coerce(data_container)
          Coerce data container to the data type, raises a ~pandera.errors.ParserError if the coercion fails
              Raises ParserError: if coercion fails
              Return type Union[Series, Index, DataFrame, ndarray]
     7.15.2.2.11.6 pandera.engines.numpy engine.Object. call
     Object.__call__(data_container)
          Coerce data container to the data type.
7.15.2.2.12 pandera.engines.pandas_engine.DateTime
```

7.15. API 191

class pandera.engines.pandas_engine.DateTime(unit='ns', tz=None, to_datetime_kwargs=<factory>)

Semantic representation of a pandas.DatetimeTZDtype.

continuous	Whether the number data type is continuous.
type	Native pandas dtype boxed by the data type.
tz	The timezone.
unit	The precision of the datetime data.
to_datetime_kwargs	Any additional kwargs passed to pandas.
	to_datetime() for coercion.

Methods

7.15.2.3 GeoPandas Dtypes

new in 0.9.0

pandera.engines.pandas_engine.Geometry

7.15.2.3.1 pandera.engines.pandas_engine.Geometry

class pandera.engines.pandas_engine.Geometry(dtype: Any)

Attributes

continuous	Whether the number data type is continuous.
type	Native pandas dtype boxed by the data type.

Methods

init	
check	Check that pandera DataType are equivalent.
coerce	Pure coerce without catching exceptions.
coerce_value	Coerce an value to a particular type.
try_coerce	Coerce data container to the data type, raises a ~pan-
	dera.errors.ParserError if the coercion fails
call	Coerce data container to the data type.

7.15.2.3.1.1 pandera.engines.pandas engine.Geometry. init

Geometry.__init__()

7.15.2.3.1.2 pandera.engines.pandas_engine.Geometry.check

Geometry.check(pandera_dtype)

Check that pandera *DataType* are equivalent.

Return type bool

7.15.2.3.1.3 pandera.engines.pandas engine.Geometry.coerce

Geometry.coerce(data_container)

Pure coerce without catching exceptions.

Return type Union[Series, Index, DataFrame]

7.15.2.3.1.4 pandera.engines.pandas_engine.Geometry.coerce_value

Geometry.coerce_value(value)

Coerce an value to a particular type.

Return type Any

7.15.2.3.1.5 pandera.engines.pandas_engine.Geometry.try_coerce

Geometry.try_coerce(data_container)

Coerce data container to the data type, raises a ~pandera.errors.ParserError if the coercion fails

Raises ParserError: if coercion fails

Return type Union[Series, Index, DataFrame]

7.15.2.3.1.6 pandera.engines.pandas engine.Geometry. call

```
Geometry.__call__(data_container)
```

Coerce data container to the data type.

7.15.2.4 Pydantic Dtypes

new in 0.10.0

pandera.engines.pandas_engine. A pydantic model datatype applying to rows in a PydanticModel dataframe.

7.15.2.4.1 pandera.engines.pandas_engine.PydanticModel

class pandera.engines.pandas_engine.PydanticModel(model)

A pydantic model datatype applying to rows in a dataframe.

Attributes

continuous	Whether the number data type is continuous.
type	Native pandas dtype boxed by the data type.

Methods

init	
check	Check that pandera <i>DataType</i> are equivalent.
coerce	Coerce pandas dataframe with pydantic record
	model.
coerce_value	Coerce an value to a particular type.
try_coerce	Coerce data container to the data type, raises a ~pan-
	dera.errors.ParserError if the coercion fails
call	Coerce data container to the data type.

7.15.2.4.1.1 pandera.engines.pandas_engine.PydanticModel.__init__

PydanticModel.__init__(model)

7.15.2.4.1.2 pandera.engines.pandas_engine.PydanticModel.check

PydanticModel.check(pandera_dtype)

Check that pandera *DataType* are equivalent.

Return type bool

7.15.2.4.1.3 pandera.engines.pandas_engine.PydanticModel.coerce

PydanticModel.coerce(data_container)

Coerce pandas dataframe with pydantic record model.

Return type DataFrame

7.15.2.4.1.4 pandera.engines.pandas engine.PydanticModel.coerce value

PydanticModel.coerce_value(value)

Coerce an value to a particular type.

Return type Any

7.15.2.4.1.5 pandera.engines.pandas_engine.PydanticModel.try_coerce

PydanticModel.try_coerce(data_container)

Coerce data container to the data type, raises a ~pandera.errors.ParserError if the coercion fails

Raises ParserError: if coercion fails

Return type Union[Series, Index, DataFrame]

7.15.2.4.1.6 pandera.engines.pandas_engine.PydanticModel.__call__

PydanticModel.__call__(data_container)

Coerce data container to the data type.

7.15.2.5 Utility functions

pandera.dtypes.is_subdtype	Returns True if first argument is lower/equal in DataType
	hierarchy.
pandera.dtypes.is_float	Return True if pandera.dtypes.DataType is a float.
pandera.dtypes.is_int	Return True if pandera.dtypes.DataType is an inte-
	ger.
pandera.dtypes.is_uint	Return True if pandera.dtypes.DataType is an un-
	signed integer.
pandera.dtypes.is_complex	Return True if pandera.dtypes.DataType is a com-
	plex number.
pandera.dtypes.is_numeric	Return True if pandera.dtypes.DataType is a com-
	plex number.
pandera.dtypes.is_bool	Return True if pandera.dtypes.DataType is a
	boolean.
pandera.dtypes.is_string	Return True if pandera.dtypes.DataType is a string.
pandera.dtypes.is_datetime	Return True if pandera.dtypes.DataType is a date-
	time.
pandera.dtypes.is_timedelta	Return True if pandera.dtypes.DataType is a
	timedelta.
pandera.dtypes.immutable	dataclasses.dataclass() decorator with different
	default values: frozen=True, init=False, repr=False.

7.15.2.5.1 pandera.dtypes.is_subdtype

```
pandera.dtypes.is_subdtype(arg1, arg2)
```

Returns True if first argument is lower/equal in DataType hierarchy.

Return type bool

7.15.2.5.2 pandera.dtypes.is float

```
pandera.dtypes.is_float(pandera_dtype)
```

Return True if pandera.dtypes.DataType is a float.

Return type bool

7.15.2.5.3 pandera.dtypes.is_int

```
pandera.dtypes.is_int(pandera_dtype)
```

Return True if pandera.dtypes.DataType is an integer.

Return type bool

7.15.2.5.4 pandera.dtypes.is_uint

```
pandera.dtypes.is_uint(pandera_dtype)
```

Return True if *pandera.dtypes.DataType* is an unsigned integer.

Return type bool

7.15.2.5.5 pandera.dtypes.is_complex

```
pandera.dtypes.is_complex(pandera_dtype)
```

Return True if *pandera.dtypes.DataType* is a complex number.

Return type bool

7.15.2.5.6 pandera.dtypes.is_numeric

```
pandera.dtypes.is_numeric(pandera_dtype)
```

Return True if *pandera.dtypes.DataType* is a complex number.

Return type bool

7.15.2.5.7 pandera.dtypes.is_bool

```
pandera.dtypes.is_bool(pandera_dtype)

Return True if pandera.dtypes.DataType is a boolean.
```

Return type bool

7.15.2.5.8 pandera.dtypes.is string

```
pandera.dtypes.is_string(pandera_dtype)
```

Return True if pandera.dtypes.DataType is a string.

Return type bool

7.15.2.5.9 pandera.dtypes.is datetime

```
pandera.dtypes.is_datetime(pandera_dtype)
```

Return True if *pandera.dtypes.DataType* is a datetime.

Return type bool

7.15.2.5.10 pandera.dtypes.is_timedelta

```
pandera.dtypes.is_timedelta(pandera_dtype)
```

Return True if pandera. dtypes. DataType is a timedelta.

Return type bool

7.15.2.5.11 pandera.dtypes.immutable

```
pandera.dtypes.immutable(pandera_dtype_cls=None, **dataclass_kwargs)
```

dataclasses.dataclass() decorator with different default values: frozen=True, init=False, repr=False.

In addition, *init=False* disables inherited __*init*__ method to ensure the DataType's default attributes are not altered during initialization.

Parameters

- **dtype** *DataType* to decorate.
- dataclass_kwargs (Any) Keywords arguments forwarded to dataclasses. dataclass().

Return type Union[Type[~_Dtype], Callable[[Type[~_Dtype]], Type[~_Dtype]]]

Returns Immutable *DataType*

7.15.2.6 Engines

pandera.engines.engine.Engine	Base Engine metaclass.
<pre>pandera.engines.numpy_engine.Engine</pre>	Numpy data type engine.
pandera.engines.pandas_engine.Engine	Pandas data type engine.

7.15.2.6.1 pandera.engines.engine.Engine

class pandera.engines.engine.Engine(name, bases, namespace, **kwargs)

Base Engine metaclass.

Keep a registry of concrete Engines.

Methods

dtype	Convert input into a Pandera DataType object.
get_registered_dtypes	Return the pandera.dtypes.DataTypes registered
	with this engine.
register_dtype	Register a Pandera DataType with the engine, as
	class decorator.
call	Call self as a function.

7.15.2.6.1.1 pandera.engines.engine.Engine.dtype

Engine.dtype(data_type)

Convert input into a Pandera DataType object.

Return type ~_DataType

7.15.2.6.1.2 pandera.engines.engine.Engine.get_registered_dtypes

Engine.get_registered_dtypes()

Return the pandera.dtypes.DataTypes registered with this engine.

Return type List[Type[DataType]]

7.15.2.6.1.3 pandera.engines.engine.Engine.register_dtype

 $\label{lem:engine} \mbox{Engine.register_dtype}(\mbox{\it pandera_dtype_\it cls=None}, *, \mbox{\it equivalents=None})$

Register a Pandera *DataType* with the engine, as class decorator.

Parameters

- pandera_dtype The DataType to register.
- **equivalents** (Optional[List[Any]]) Equivalent scalar data type classes or non-parametrized data type instances.

Note: The classmethod from_parametrized_dtype will also be registered. See *here* for more usage details.

Example

```
>>> import pandera as pa
>>>
>>> class MyDataType(pa.DataType):
...    pass
>>>
>>> class MyEngine(
...    metaclass=pa.engines.engine.Engine,
...    base_pandera_dtypes=MyDataType,
... ):
...    pass
>>>
>>> @MyEngine.register_dtype(equivalents=[bool])
... class MyBool(MyDataType):
...    pass
```

Return type Callable

7.15.2.6.1.4 pandera.engines.engine.Engine.__call__

```
Engine.__call__(*args, **kwargs)

Call self as a function.
```

7.15.2.6.2 pandera.engines.numpy_engine.Engine

class pandera.engines.numpy_engine.Engine
 Numpy data type engine.

Methods

dtype	Convert input into a numpy-compatible Pandera
	DataType object.

7.15.2.6.2.1 pandera.engines.numpy engine.Engine.dtype

classmethod Engine.dtype(data_type)

Convert input into a numpy-compatible Pandera *DataType* object.

Return type DataType

7.15.2.6.3 pandera.engines.pandas engine.Engine

class pandera.engines.pandas_engine.Engine

Pandas data type engine.

Methods

dtype	Convert input into a pandas-compatible Pandera
	DataType object.
numpy_dtype	Convert a Pandera dtype.

7.15.2.6.3.1 pandera.engines.pandas_engine.Engine.dtype

classmethod Engine.dtype(data_type)

Convert input into a pandas-compatible Pandera *DataType* object.

Return type DataType

7.15.2.6.3.2 pandera.engines.pandas_engine.Engine.numpy_dtype

classmethod Engine.numpy_dtype(pandera_dtype)

Convert a Pandera dtype.

Return type dtype

7.15.3 Schema Models

7.15.3.1 Schema Model

<pre>pandera.model.SchemaModel(*args, **kwargs)</pre>	Definition of a DataFrameSchema.	

7.15.3.1.1 pandera.model.SchemaModel

class pandera.model.SchemaModel(*args, **kwargs)

Definition of a DataFrameSchema.

new in 0.5.0

See the *User Guide* for more.

Check if all columns in a dataframe have a column in the Schema.

Parameters

- **check_obj** (*pd.DataFrame*) the dataframe to be validated.
- head validate the first n rows. Rows overlapping with tail or sample are de-duplicated.
- tail validate the last n rows. Rows overlapping with head or sample are de-duplicated.
- sample validate a random sample of n rows. Rows overlapping with head or tail are deduplicated.
- random_state random seed for the sample argument.
- lazy if True, lazily evaluates dataframe against all validation checks and raises a SchemaErrors. Otherwise, raise SchemaError as soon as one occurs.
- **inplace** if True, applies coercion to the object of validation, otherwise creates a copy of the data.

Returns validated DataFrame

Raises SchemaError – when DataFrame violates built-in or custom checks.

Example

Calling schema.validate returns the dataframe.

```
>>> import pandas as pd
>>> import pandera as pa
>>>
>>> df = pd.DataFrame({
        "probability": [0.1, 0.4, 0.52, 0.23, 0.8, 0.76],
        "category": ["dog", "dog", "cat", "duck", "dog", "dog"]
. . .
... })
>>>
>>> schema_withchecks = pa.DataFrameSchema({
        "probability": pa.Column(
            float, pa.Check(lambda s: (s \ge 0) \& (s \le 1))),
. . .
        # check that the "category" column contains a few discrete
        # values, and the majority of the entries are dogs.
        "category": pa.Column(
            str, [
                pa.Check(lambda s: s.isin(["dog", "cat", "duck"])),
. . .
                pa.Check(lambda s: (s == "dog").mean() > 0.5),
            1),
. . .
... })
>>> schema_withchecks.validate(df)[["probability", "category"]]
```

(continues on next page)

(continued from previous page)

	probability	category
0	0.10	dog
1	0.40	dog
2	0.52	cat
3	0.23	duck
4	0.80	dog
5	0.76	dog

Methods

example example	Create a hypothesis strategy for generating a
	DataFrame.
strategy	Create a hypothesis strategy for generating a
	DataFrame.
to_schema	Create DataFrameSchema from the SchemaModel.
to_yaml	Convert Schema to yaml using io.to_yaml.
validate	Check if all columns in a dataframe have a column in
	the Schema.

7.15.3.1.1.1 pandera.model.SchemaModel.example

classmethod SchemaModel.example(cls, *, size=None)

Create a hypothesis strategy for generating a DataFrame.

Parameters

- **size** (Optional[int]) number of elements to generate
- n_regex_columns number of regex columns to generate.

Return type DataFrameBase[~TSchemaModel]

Returns a strategy that generates pandas DataFrame objects.

7.15.3.1.1.2 pandera.model.SchemaModel.strategy

classmethod SchemaModel.strategy(cls, *, size=None)

Create a hypothesis strategy for generating a DataFrame.

Parameters

- **size** (Optional[int]) number of elements to generate
- n_regex_columns number of regex columns to generate.

Returns a strategy that generates pandas DataFrame objects.

7.15.3.1.1.3 pandera.model.SchemaModel.to schema

classmethod SchemaModel.to_schema()

Create DataFrameSchema from the SchemaModel.

Return type DataFrameSchema

7.15.3.1.1.4 pandera.model.SchemaModel.to yaml

```
classmethod SchemaModel.to_yaml(stream=None)
```

Convert Schema to yaml using io.to_yaml.

7.15.3.1.1.5 pandera.model.SchemaModel.validate

classmethod SchemaModel.**validate**(*check_obj*, *head=None*, *tail=None*, *sample=None*, *random_state=None*, *lazy=False*, *inplace=False*)

Check if all columns in a dataframe have a column in the Schema.

Parameters

- **check_obj** (*pd.DataFrame*) the dataframe to be validated.
- **head** (Optional[int]) validate the first n rows. Rows overlapping with *tail* or *sample* are de-duplicated.
- tail (Optional[int]) validate the last n rows. Rows overlapping with *head* or *sample* are de-duplicated.
- **sample** (Optional[int]) validate a random sample of n rows. Rows overlapping with *head* or *tail* are de-duplicated.
- random_state (Optional[int]) random seed for the sample argument.
- lazy (bool) if True, lazily evaluates dataframe against all validation checks and raises a SchemaErrors. Otherwise, raise SchemaError as soon as one occurs.
- **inplace** (bool) if True, applies coercion to the object of validation, otherwise creates a copy of the data.

Return type DataFrameBase[~TSchemaModel]

Returns validated DataFrame

Raises SchemaError – when DataFrame violates built-in or custom checks.

Example

Calling schema.validate returns the dataframe.

(continues on next page)

(continued from previous page)

```
schema_withchecks = pa.DataFrameSchema({
        "probability": pa.Column(
            float, pa.Check(lambda s: (s >= 0) & (s <= 1))),
. . .
. . .
        # check that the "category" column contains a few discrete
        # values, and the majority of the entries are dogs.
        "category": pa.Column(
            str, [
. . .
                 pa.Check(lambda s: s.isin(["dog", "cat", "duck"])),
                 pa.Check(lambda s: (s == "dog").mean() > 0.5),
. . .
            ]),
... })
>>>
>>> schema_withchecks.validate(df)[["probability", "category"]]
   probability category
0
          0.10
                     doa
1
          0.40
                     dog
2
          0.52
                     cat
3
          0.23
                    duck
4
          0.80
                     dog
5
          0.76
                     dog
```

7.15.3.2 Model Components

<pre>pandera.model_components.Field(*[, eq, ne,])</pre>	Used to provide extra information about a field of a SchemaModel.
<pre>pandera.model_components.check(*fields[, regex])</pre>	Decorator to make SchemaModel method a col- umn/index check function.
<pre>pandera.model_components. dataframe_check([fn])</pre>	Decorator to make SchemaModel method a dataframewide check function.

7.15.3.2.1 pandera.model_components.Field

```
pandera.model_components.Field(*, eq=None, ne=None, gt=None, ge=None, lt=None, le=None, in_range=None, isin=None, notin=None, str_contains=None, str_endswith=None, str_length=None, str_matches=None, str_startswith=None, nullable=False, unique=False, coerce=False, regex=False, ignore_na=True, raise_warning=False, n_failure_cases=None, alias=None, check_name=None, dtype_kwargs=None, title=None, description=None, **kwargs)
```

Used to provide extra information about a field of a SchemaModel.

new in 0.5.0

Some arguments apply only to numeric dtypes and some apply only to str. See the *User Guide* for more information.

The keyword-only arguments from eq to str_startswith are dispatched to the built-in *Check* methods.

Parameters

• nullable (bool) – Whether or not the column/index can contain null values.

- unique (bool) Whether column values should be unique.
- **coerce** (bool) coerces the data type if True.
- regex (bool) whether or not the field name or alias is a regex pattern.
- **ignore_na** (bool) whether or not to ignore null values in the checks.
- raise_warning (bool) raise a warning instead of an Exception.
- n_failure_cases (Optional[int]) report the first n unique failure cases. If None, report
 all failure cases.
- alias (Optional[Any]) The public name of the column/index.
- **check_name** (Optional[bool]) Whether to check the name of the column/index during validation. *None* is the default behavior, which translates to *True* for columns and multi-index, and to *False* for a single index.
- dtype_kwargs (Optional[Dict[str, Any]]) The parameters to be forwarded to the type
 of the field.
- title (Optional[str]) A human-readable label for the field.
- description (Optional[str]) An arbitrary textual description of the field.
- kwargs Specify custom checks that have been registered with the register_check_method decorator.

Return type Any

7.15.3.2.2 pandera.model components.check

pandera.model_components.check(*fields, regex=False, **check_kwargs)

Decorator to make SchemaModel method a column/index check function.

new in 0.5.0

This indicates that the decorated method should be used to validate a field (column or index). The method will be converted to a classmethod. Therefore its signature must start with *cls* followed by regular check arguments. See the *User Guide* for more.

Parameters

- **_fn** Method to decorate.
- **check_kwargs** Keywords arguments forwarded to Check.

Return type Callable[[Union[classmethod, Callable[..., Any]]], classmethod]

7.15.3.2.3 pandera.model components.dataframe check

pandera.model_components.dataframe_check(_fn=None, **check_kwargs)

Decorator to make SchemaModel method a dataframe-wide check function.

new in 0.5.0

Decorate a method on the SchemaModel indicating that it should be used to validate the DataFrame. The method will be converted to a classmethod. Therefore its signature must start with *cls* followed by regular check arguments. See the *User Guide* for more.

Parameters check_kwargs – Keywords arguments forwarded to Check.

Return type Callable[[Union[classmethod, Callable[..., Any]]], classmethod]

7.15.3.3 Typing

pandera.typing	Typing module.

7.15.3.3.1 pandera.typing

Typing module.

For backwards compatibility, pandas types are exposed to the top-level scope of the typing module.

Pandas Types

DataFrame([data, index, columns, dtype, copy])	A generic type for pandas.DataFrame.
<pre>Index([data, dtype, copy, name, tupleize_cols])</pre>	Representation of pandas.Index, only used for type an-
	notation.
Series([data, index, dtype, name, copy,])	Representation of pandas. Series, only used for type an-
	notation.

GeoPandas Types

<pre>geopandas.GeoDataFrame([data, geometry, crs])</pre>	A generic type for geopandas.GeoDataFrame.
geopandas.GeoSeries([data, index, crs])	Representation of geopandas.GeoSeries, only used for
	type annotation.

Dask Types

dask.DataFrame(dsk, name, meta, divisions)	Representation of dask.dataframe.DataFrame, only used
	for type annotation.
dask.Series(dsk, name, meta, divisions)	Representation of pandas. Series, only used for type an-
	notation.
dask.Index(dsk, name, meta, divisions)	Representation of pandas.Index, only used for type an-
	notation.

Pyspark Pandas Types

<pre>pyspark.DataFrame([data, index, columns,])</pre>	Representation of dask.dataframe.DataFrame, only used
	for type annotation.
pyspark.Series([data, index, dtype, name,])	Representation of pandas. Series, only used for type an-
	notation.
pyspark.Index([data, dtype, copy, name,])	Representation of pandas.Index, only used for type an-
	notation.

Modin Types

<pre>pyspark.DataFrame([data, index, columns,])</pre>	Representation of dask.dataframe.DataFrame, only used
	for type annotation.
pyspark.Series([data, index, dtype, name,])	Representation of pandas. Series, only used for type an-
	notation.
pyspark.Index([data, dtype, copy, name,])	Representation of pandas.Index, only used for type an-
	notation.

FastAPI Types

fastapi.UploadFile(data, filename, file,)	Pandera-specific subclass of fastapi. Upload File.

7.15.3.3.1.1 pandera.typing.fastapi.UploadFile

class pandera.typing.fastapi.UploadFile(data, filename, file, *args, **kwargs)

Pandera-specific subclass of fastapi. Upload File.

This type uses pandera.typing.DataFrame to read files into dataframe format based on the pandera.models.SchemaModel configuration.

Initialize UploadFile object that has a data property that contains validated data.

Parameters data (Any) – pandera-validated data

Filename

```
__init__(data, filename, file, *args, **kwargs)
```

Initialize UploadFile object that has a data property that contains validated data.

Parameters data (Any) – pandera-validated data

Filename

Methods

init(data, filename, file, *args, **kwargs)	Initialize UploadFile object that has a data property
	that contains validated data.
close()	
	rtype None
<pre>pydantic_validate(obj, field)</pre>	Pydantic validation method for validating dataframes
	in the context of a file upload.
read([size])	
	<pre>rtype Union[bytes, str]</pre>
seek(offset)	
	rtype None
	· ·
validate(v)	
	rtype Any
	••
write(data)	
	rtype None
	V

Attributes

data			
spool_max_size			

Serialization Formats

formats.Formats(value)	Data container serialization formats.

7.15.3.3.1.2 pandera.typing.formats.Formats

class pandera.typing.formats.Formats(value)

Data container serialization formats.

The values of this enum specify the valid values taken by the to_format and from_format attributes in <code>BaseConfig</code> when specifying a <code>SchemaModel</code>.

__init__()

Attributes

CSV	comma-separated values file
dict	python dictionary
json	json file
feather	feather file format.
parquet	parquet file format.
pickle	python pickle file format

DataTypes

Bool()	Semantic representation of a boolean data type.
DateTime	alias of pandera.dtypes.Timestamp
Timedelta()	Semantic representation of a delta time data type.
Category([categories, ordered])	Semantic representation of a categorical data type.
Float()	Semantic representation of a floating data type.
Float16()	Semantic representation of a floating data type stored in 16 bits.
Float32()	Semantic representation of a floating data type stored in
	32 bits.
Float64()	Semantic representation of a floating data type stored in 64 bits.
Int()	Semantic representation of an integer data type.
Int8()	Semantic representation of an integer data type stored in
	8 bits.
Int16()	Semantic representation of an integer data type stored in 16 bits.
Int32()	Semantic representation of an integer data type stored in
	32 bits.
Int64()	Semantic representation of an integer data type stored in
	64 bits.
UInt8()	Semantic representation of an unsigned integer data type stored in 8 bits.
UInt16()	Semantic representation of an unsigned integer data type
	stored in 16 bits.
UInt32()	Semantic representation of an unsigned integer data type stored in 32 bits.
UInt64()	Semantic representation of an unsigned integer data type
	stored in 64 bits.
INT8()	Semantic representation of a pandas.Int8Dtype.
INT16()	Semantic representation of a pandas.Int16Dtype.
INT32()	Semantic representation of a pandas.Int32Dtype.
INT64()	Semantic representation of a pandas.Int64Dtype.
UINT8()	Semantic representation of a pandas.UInt8Dtype.
UINT16()	Semantic representation of a pandas.UInt16Dtype.
UINT32()	Semantic representation of a pandas.UInt32Dtype.
UINT64()	Semantic representation of a pandas.UInt64Dtype.
Object()	Semantic representation of a numpy.object
String()	Semantic representation of a string data type.
STRING([storage])	Semantic representation of a pandas.StringDtype.

7.15.3.4 Config

pandera.model.BaseConfig	Define DataFrameSchema-wide options.
--------------------------	--------------------------------------

7.15.3.4.1 pandera.model.BaseConfig

${\bf class} \ {\tt pandera.model.BaseConfig}$

Bases: object

Define DataFrameSchema-wide options.

new in 0.5.0

Attributes

coerce	coerce types of all schema components
description	arbitrary textual description
dtype	datatype of the dataframe.
from_format	data format before validation.
from_format_kwargs	a dictionary keyword arguments to pass into the
	reader function that converts the object of type
	<pre>from_format to a pandera-validate-able data struc-</pre>
	ture.
multiindex_coerce	coerce types of all MultiIndex components
multiindex_name	name of multiindex
multiindex_ordered	validate MultiIndex in order
multiindex_strict	make sure all specified columns are in validated Mul-
	tiIndex - if "filter", removes indexes not specified
	in the schema
name	name of schema
ordered	validate columns order
strict	make sure all specified columns are in the validated
	dataframe - if "filter", removes columns not spec-
	ified in the schema
title	human-readable label for schema
to_format	data format to serialize into after validation.
to_format_kwargs	a dictionary keyword arguments to pass into the
	writer function that converts the pandera-validate-
	able object to type to_format.
unique	make sure certain column combinations are unique
unique_column_names	make sure dataframe column names are unique

7.15.4 Decorators

pandera.decorators.check_input	Validate function argument when function is called.
pandera.decorators.check_output	Validate function output.
pandera.decorators.check_io	Check schema for multiple inputs and outputs.
pandera.decorators.check_types	Validate function inputs and output based on type anno-
	tations.

7.15.4.1 pandera.decorators.check_input

pandera.decorators.check_input(schema, obj_getter=None, head=None, tail=None, sample=None, random_state=None, lazy=False, inplace=False)

Validate function argument when function is called.

This is a decorator function that validates the schema of a dataframe argument in a function.

Parameters

- schema (Union[DataFrameSchema, SeriesSchema]) dataframe/series schema object
- **obj_getter** (Union[int, str, None]) (Default value = None) if int, obj_getter refers to the the index of the pandas dataframe/series to be validated in the args part of the function signature. If str, obj_getter refers to the argument name of the pandas dataframe/series in the function signature. This works even if the series/dataframe is passed in as a positional argument when the function is called. If None, assumes that the dataframe/series is the first argument of the decorated function
- **head** (Optional[int]) validate the first n rows. Rows overlapping with *tail* or *sample* are de-duplicated.
- **tail** (Optional[int]) validate the last n rows. Rows overlapping with *head* or *sample* are de-duplicated.
- **sample** (Optional[int]) validate a random sample of n rows. Rows overlapping with *head* or *tail* are de-duplicated.
- random_state (Optional[int]) random seed for the sample argument.
- lazy (bool) if True, lazily evaluates dataframe against all validation checks and raises a SchemaErrors. Otherwise, raise SchemaError as soon as one occurs.
- **inplace** (bool) if True, applies coercion to the object of validation, otherwise creates a copy of the data.

Return type Callable[[~F], ~F]

Returns wrapped function

Example

Check the input of a decorated function.

```
>>> import pandas as pd
>>> import pandera as pa
>>>
>>>
>>>
>>>
>>>
>>>
>>>
>>> schema = pa.DataFrameSchema({"column": pa.Column(int)})
>>>>
```

(continues on next page)

(continued from previous page)

```
>>> @pa.check_input(schema)
    def transform_data(df: pd.DataFrame) -> pd.DataFrame:
        df["doubled_column"] = df["column"] * 2
        return df
>>>
>>> df = pd.DataFrame({
        "column": range(5),
... })
>>>
>>> transform_data(df)
   column doubled_column
0
        0
1
        1
                         2
2
        2
                         4
3
        3
                         6
4
        4
                         8
```

See *here* for more usage details.

7.15.4.2 pandera.decorators.check_output

pandera.decorators.check_output(schema, obj_getter=None, head=None, tail=None, sample=None, random_state=None, lazy=False, inplace=False)

Validate function output.

Similar to input validator, but validates the output of the decorated function.

Parameters

- **schema** (Union[DataFrameSchema, SeriesSchema]) dataframe/series schema object
- **obj_getter** (Union[str, int, Callable, None]) (Default value = None) if int, assumes that the output of the decorated function is a list-like object, where obj_getter is the index of the pandas data dataframe/series to be validated. If str, expects that the output is a dict-like object, and obj_getter is the key pointing to the dataframe/series to be validated. If a callable is supplied, it expects the output of decorated function and should return the dataframe/series to be validated.
- **head** (Optional[int]) validate the first n rows. Rows overlapping with *tail* or *sample* are de-duplicated.
- tail (Optional[int]) validate the last n rows. Rows overlapping with *head* or *sample* are de-duplicated.
- **sample** (Optional[int]) validate a random sample of n rows. Rows overlapping with *head* or *tail* are de-duplicated.
- random_state (Optional[int]) random seed for the sample argument.
- lazy (bool) if True, lazily evaluates dataframe against all validation checks and raises a SchemaErrors. Otherwise, raise SchemaError as soon as one occurs.
- **inplace** (bool) if True, applies coercion to the object of validation, otherwise creates a copy of the data.

Return type Callable[[~F], ~F]

Returns wrapped function

Example

Check the output a decorated function.

```
>>> import pandas as pd
>>> import pandera as pa
>>>
>>>
>>> schema = pa.DataFrameSchema(
        columns={"doubled_column": pa.Column(int)},
        checks=pa.Check(
            lambda df: df["doubled_column"] == df["column"] * 2
        )
. . .
    )
. . .
>>>
>>> @pa.check_output(schema)
    def transform_data(df: pd.DataFrame) -> pd.DataFrame:
        df["doubled_column"] = df["column"] * 2
        return df
. . .
>>>
>>> df = pd.DataFrame({"column": range(5)})
>>>
>>> transform_data(df)
   column doubled_column
0
        0
                         0
        1
                         2
1
2
        2
                         4
3
        3
                         6
4
        4
                         8
```

See *here* for more usage details.

7.15.4.3 pandera.decorators.check_io

Check schema for multiple inputs and outputs.

See *here* for more usage details.

Parameters

- **head** (Optional[int]) validate the first n rows. Rows overlapping with *tail* or *sample* are de-duplicated.
- **tail** (Optional[int]) validate the last n rows. Rows overlapping with *head* or *sample* are de-duplicated.
- **sample** (Optional[int]) validate a random sample of n rows. Rows overlapping with *head* or *tail* are de-duplicated.
- random_state (Optional[int]) random seed for the sample argument.
- lazy (bool) if True, lazily evaluates dataframe against all validation checks and raises a SchemaErrors. Otherwise, raise SchemaError as soon as one occurs.
- **inplace** (bool) if True, applies coercion to the object of validation, otherwise creates a copy of the data.

- out (Union[DataFrameSchema, SeriesSchema, Tuple[Union[str, int, Callable], Union[DataFrameSchema, SeriesSchema]], List[Tuple[Union[str, int, Callable], Union[DataFrameSchema, SeriesSchema]]], None]) this should be a schema object if the function outputs a single dataframe/series. It can be a two-tuple, where the first element is a string, integer, or callable that fetches the pandas data structure in the output, and the second element is the schema to validate against. For multiple outputs, specify a list of two-tuples following the above structure.
- **inputs** (Union[DataFrameSchema, SeriesSchema]) kwargs keys should be the argument name in the decorated function and values should be the schema used to validate the pandas data structure referenced by the argument name.

```
Return type Callable[[~F], ~F]
Returns wrapped function
```

7.15.4.4 pandera.decorators.check_types

```
pandera.decorators.check_types(wrapped: pandera.decorators.F, *, head: Optional[int] = 'None', tail: Optional[int] = 'None', sample: Optional[int] = 'None', random_state: Optional[int] = 'None', lazy: bool = 'False', inplace: bool = 'False') \rightarrow pandera.decorators.F pandera.decorators.check_types(wrapped: None = None, *, head: Optional[int] = 'None', tail: Optional[int] = 'None', sample: Optional[int] = 'None', random_state: Optional[int] = 'None', lazy: bool = 'False', inplace: bool = 'False') \rightarrow Callable[[pandera.decorators.F], pandera.decorators.F]
```

Validate function inputs and output based on type annotations.

See the *User Guide* for more.

Parameters

- **wrapped** the function to decorate.
- with_pydantic use pydantic.validate_arguments to validate inputs. This function is still needed to validate function outputs.
- **head** (Optional[int]) validate the first n rows. Rows overlapping with *tail* or *sample* are de-duplicated.
- **tail** (Optional[int]) validate the last n rows. Rows overlapping with *head* or *sample* are de-duplicated.
- **sample** (Optional[int]) validate a random sample of n rows. Rows overlapping with *head* or *tail* are de-duplicated.
- random_state (Optional[int]) random seed for the sample argument.
- lazy (bool) if True, lazily evaluates dataframe against all validation checks and raises a SchemaErrors. Otherwise, raise SchemaError as soon as one occurs.
- **inplace** (bool) if True, applies coercion to the object of validation, otherwise creates a copy of the data.

Return type Callable

7.15.5 Schema Inference

pandera.schema_inference.infer_schema	Infer schema for pandas DataFrame or Series object.
---------------------------------------	---

7.15.5.1 pandera.schema inference.infer schema

```
pandera.schema_inference.infer_schema(pandas_obj: pandas.core.series.Series) \rightarrow pandera.schemas.SeriesSchema

pandera.schema_inference.infer_schema(pandas_obj: pandas.core.frame.DataFrame) \rightarrow pandera.schemas.DataFrameSchema
```

Infer schema for pandas DataFrame or Series object.

Parameters pandas_obj – DataFrame or Series object to infer.

Returns DataFrameSchema or SeriesSchema

Raises TypeError if pandas_obj is not expected type.

7.15.6 IO Utilities

The io module and built-in Hypothesis checks require a pandera installation with the corresponding extension, see the *installation* instructions for more details.

pandera.io.from_yaml	Create DataFrameSchema from yaml file.
pandera.io.to_yaml	Write DataFrameSchema to yaml file.
pandera.io.to_script	Write DataFrameSchema to a python script.

7.15.6.1 pandera.io.from_yaml

pandera.io.from_yaml(yaml_schema)

Create DataFrameSchema from yaml file.

Parameters yaml_schema – str or Path to yaml schema, or serialized yaml string.

Returns dataframe schema.

7.15.6.2 pandera.io.to yaml

pandera.io.to_yaml(dataframe_schema, stream=None)

Write DataFrameSchema to yaml file.

Parameters

- dataframe_schema schema to write to file or dump to string.
- **stream** file stream to write to. If None, dumps to string.

Returns yaml string if stream is None, otherwise returns None.

7.15.6.3 pandera.io.to script

pandera.io.to_script(dataframe_schema, path_or_buf=None)

Write DataFrameSchema to a python script.

Parameters

- dataframe_schema schema to write to file or dump to string.
- **path_or_buf** filepath or buf stream to write to. If None, outputs string representation of the script.

Returns yaml string if stream is None, otherwise returns None.

7.15.7 Data Synthesis Strategies

pandera.strategies

Generate synthetic data from a schema definition.

7.15.7.1 pandera.strategies

Generate synthetic data from a schema definition.

new in 0.6.0

This module is responsible for generating data based on the type and check constraints specified in a pandera schema. It's built on top of the hypothesis package to compose strategies given multiple checks specified in a schema.

See the *user guide* for more details.

Create a data object describing a column in a DataFrame.

Parameters

- pandera_dtype (Union[DataType, DataType]) pandera.dtypes.DataType instance.
- **strategy** (Optional[SearchStrategy]) an optional hypothesis strategy. If specified, the pandas dtype strategy will be chained onto this strategy.
- **checks** (Optional[Sequence]) sequence of *Check* s to constrain the values of the data in the column/index.
- unique (bool) whether or not generated Series contains unique values.
- name (Optional[str]) name of the Series.

Returns a column object.

Strategy to generate a pandas DataFrame.

Parameters

- pandera_dtype (Optional[DataType]) pandera.dtypes.DataType instance.
- **strategy** (Optional[SearchStrategy]) if specified, this will raise a BaseStrategyOnlyError, since it cannot be chained to a prior strategy.

- **columns** (Optional[Dict]) a dictionary where keys are column names and values are *Column* objects.
- **checks** (Optional[Sequence]) sequence of *Check* s to constrain the values of the data at the dataframe level.
- **unique** (Optional[List[str]]) a list of column names that should be jointly unique.
- index (Optional[Any]) Index or MultiIndex schema component.
- **size** (Optional[int]) number of elements in the Series.
- n_regex_columns (int) number of regex columns to generate.

Returns hypothesis strategy.

pandera.strategies.eq_strategy(pandera_dtype, strategy=None, *, value)

Strategy to generate a single value.

Parameters

- pandera_dtype (Union[DataType, DataType]) pandera.dtypes.DataType instance.
- **strategy** (Optional[SearchStrategy]) an optional hypothesis strategy. If specified, the pandas dtype strategy will be chained onto this strategy.
- value (Any) value to generate.

Return type SearchStrategy

Returns hypothesis strategy

pandera.strategies.field_element_strategy(pandera_dtype, strategy=None, *, checks=None)

Strategy to generate elements of a column or index.

Parameters

- pandera_dtype (Union[DataType, DataType]) pandera.dtypes.DataType instance.
- **strategy** (Optional[SearchStrategy]) an optional hypothesis strategy. If specified, the pandas dtype strategy will be chained onto this strategy.
- **checks** (Optional[Sequence]) sequence of *Check* s to constrain the values of the data in the column/index.

Return type SearchStrategy

Returns hypothesis strategy

pandera.strategies.ge_strategy(pandera_dtype, strategy=None, *, min_value)

Strategy to generate values greater than or equal to a minimum value.

Parameters

- pandera_dtype (Union[DataType, DataType]) pandera.dtypes.DataType instance.
- **strategy** (Optional[SearchStrategy]) an optional hypothesis strategy. If specified, the pandas dtype strategy will be chained onto this strategy.
- min_value (Union[int, float]) generate values greater than or equal to this.

Return type SearchStrategy

Returns hypothesis strategy

pandera_strategies.gt_strategy(pandera_dtype, strategy=None, *, min_value)

Strategy to generate values greater than a minimum value.

Parameters

- pandera_dtype (Union[DataType, DataType]) pandera.dtypes.DataType instance.
- **strategy** (Optional[SearchStrategy]) an optional hypothesis strategy. If specified, the pandas dtype strategy will be chained onto this strategy.
- min_value (Union[int, float]) generate values larger than this.

Return type SearchStrategy

Returns hypothesis strategy

Strategy to generate values within a particular range.

Parameters

- pandera_dtype (Union[DataType, DataType]) pandera.dtypes.DataType instance.
- **strategy** (Optional[SearchStrategy]) an optional hypothesis strategy. If specified, the pandas dtype strategy will be chained onto this strategy.
- **min_value** (Union[int, float]) generate values greater than this.
- max_value (Union[int, float]) generate values less than this.
- **include_min** (bool) include min_value in generated data.
- include_max (bool) include max_value in generated data.

Return type SearchStrategy

Returns hypothesis strategy

Strategy to generate a pandas Index.

Parameters

- pandera_dtype (Union[DataType, DataType]) pandera.dtypes.DataType instance.
- **strategy** (Optional[SearchStrategy]) an optional hypothesis strategy. If specified, the pandas dtype strategy will be chained onto this strategy.
- **checks** (Optional[Sequence]) sequence of *Check* s to constrain the values of the data in the column/index.
- nullable (bool) whether or not generated Series contains null values.
- unique (bool) whether or not generated Series contains unique values.
- name (Optional[str]) name of the Series.
- **size** (Optional[int]) number of elements in the Series.

Returns hypothesis strategy.

 $pandera_strategies. \textbf{isin_strategy} (pandera_dtype, \textit{strategy=None}, *, \textit{allowed_values})$

Strategy to generate values within a finite set.

Parameters

- pandera_dtype (Union[DataType, DataType]) pandera.dtypes.DataType instance.
- **strategy** (Optional[SearchStrategy]) an optional hypothesis strategy. If specified, the pandas dtype strategy will be chained onto this strategy.
- allowed_values (Sequence[Any]) set of allowable values.

Return type SearchStrategy

Returns hypothesis strategy

pandera.strategies.le_strategy(pandera_dtype, strategy=None, *, max_value)

Strategy to generate values less than or equal to a maximum value.

Parameters

- $\bullet \ pandera_dtype \ (\texttt{Union}[\texttt{DataType}, \texttt{DataType}]) pandera_dtypes. \textit{DataType} \ instance.$
- **strategy** (Optional[SearchStrategy]) an optional hypothesis strategy. If specified, the pandas dtype strategy will be chained onto this strategy.
- max_value (Union[int, float]) generate values less than or equal to this.

Return type SearchStrategy

Returns hypothesis strategy

pandera.strategies.lt_strategy(pandera_dtype, strategy=None, *, max_value)

Strategy to generate values less than a maximum value.

Parameters

- pandera_dtype (Union[DataType, DataType]) pandera.dtypes.DataType instance.
- **strategy** (Optional[SearchStrategy]) an optional hypothesis strategy. If specified, the pandas dtype strategy will be chained onto this strategy.
- max_value (Union[int, float]) generate values less than this.

Return type SearchStrategy

Returns hypothesis strategy

Strategy to generate a pandas MultiIndex object.

Parameters

- pandera_dtype (Optional[DataType]) pandera.dtypes.DataType instance.
- **strategy** (Optional[SearchStrategy]) an optional hypothesis strategy. If specified, the pandas dtype strategy will be chained onto this strategy.
- indexes (Optional[List]) a list of *Index* objects.
- **size** (Optional[int]) number of elements in the Series.

Returns hypothesis strategy.

pandera.strategies.ne_strategy(pandera dtype, strategy=None, *, value)

Strategy to generate anything except for a particular value.

Parameters

• pandera_dtype (Union[DataType, DataType]) - pandera.dtypes.DataType instance.

- **strategy** (Optional[SearchStrategy]) an optional hypothesis strategy. If specified, the pandas dtype strategy will be chained onto this strategy.
- value (Any) value to avoid.

Return type SearchStrategy

Returns hypothesis strategy

pandera.strategies.notin_strategy(pandera_dtype, strategy=None, *, forbidden_values)

Strategy to generate values excluding a set of forbidden values

Parameters

- pandera_dtype (Union[DataType, DataType]) pandera.dtypes.DataType instance.
- **strategy** (Optional[SearchStrategy]) an optional hypothesis strategy. If specified, the pandas dtype strategy will be chained onto this strategy.
- **forbidden_values** (Sequence[Any]) set of forbidden values.

Return type SearchStrategy

Returns hypothesis strategy

Create numpy strategy for complex numbers.

Parameters

- **dtype** numpy complex number datatype
- min_value (complex) minimum value, must be complex number
- max_value (Optional[complex]) maximum value, must be complex number

Returns hypothesis strategy

pandera.strategies.numpy_time_dtypes(dtype, min_value=None, max_value=None)

Create numpy strategy for datetime and timedelta data types.

Parameters

- **dtype** (Union[dtype, DatetimeTZDtype]) numpy datetime or timedelta datatype
- min_value minimum value of the datatype to create
- max_value maximum value of the datatype to create

Returns hypothesis strategy

pandera.strategies.pandas_dtype_strategy(pandera_dtype, strategy=None, **kwargs)

Strategy to generate data from a pandera.dtypes.DataType.

Parameters

- pandera_dtype (DataType) pandera.dtypes.DataType instance.
- **strategy** (Optional[SearchStrategy]) an optional hypothesis strategy. If specified, the pandas dtype strategy will be chained onto this strategy.

Kwargs key-word arguments passed into hypothesis.extra.numpy.from_dtype . For date-time, timedelta, and complex number datatypes, these arguments are passed into numpy_time_dtypes() and numpy_complex_dtypes().

Return type SearchStrategy

Returns hypothesis strategy

```
pandera.strategies.register_check_strategy(strategy_fn)
```

Decorate a Check method with a strategy.

This should be applied to a built-in *Check* method.

Parameters strategy_fn (Callable[..., SearchStrategy]) – add strategy to a check, using check statistics to generate a hypothesis strategy.

Strategy to generate a pandas Series.

Parameters

- pandera_dtype (Union[DataType, DataType]) pandera.dtypes.DataType instance.
- **strategy** (Optional[SearchStrategy]) an optional hypothesis strategy. If specified, the pandas dtype strategy will be chained onto this strategy.
- **checks** (Optional[Sequence]) sequence of *Check* s to constrain the values of the data in the column/index.
- nullable (bool) whether or not generated Series contains null values.
- **unique** (bool) whether or not generated Series contains unique values.
- name (Optional[str]) name of the Series.
- **size** (Optional[int]) number of elements in the Series.

Returns hypothesis strategy.

pandera.strategies.str_contains_strategy(pandera dtype, strategy=None, *, pattern)

Strategy to generate strings that contain a particular pattern.

Parameters

- pandera_dtype (Union[DataType, DataType]) pandera.dtypes.DataType instance.
- **strategy** (Optional[SearchStrategy]) an optional hypothesis strategy. If specified, the pandas dtype strategy will be chained onto this strategy.
- pattern (str) regex pattern.

Return type SearchStrategy

Returns hypothesis strategy

 $pandera_strategies. \textbf{str_endswith_strategy}(pandera_dtype, \textit{strategy=None}, *, \textit{string})$

Strategy to generate strings that end with a specific string pattern.

Parameters

- pandera_dtype (Union[DataType, DataType]) pandera.dtypes.DataType instance.
- **strategy** (Optional[SearchStrategy]) an optional hypothesis strategy. If specified, the pandas dtype strategy will be chained onto this strategy.
- **string** (str) string pattern.

Return type SearchStrategy

Returns hypothesis strategy

pandera.strategies.str_length_strategy(pandera_dtype, strategy=None, *, min_value, max_value)

Strategy to generate strings of a particular length

Parameters

- pandera_dtype (Union[DataType, DataType]) pandera.dtypes.DataType instance.
- **strategy** (Optional[SearchStrategy]) an optional hypothesis strategy. If specified, the pandas dtype strategy will be chained onto this strategy.
- min_value (int) minimum string length.
- max_value (int) maximum string length.

Return type SearchStrategy

Returns hypothesis strategy

pandera.strategies.str_matches_strategy(pandera_dtype, strategy=None, *, pattern)

Strategy to generate strings that patch a regex pattern.

Parameters

- pandera_dtype (Union[DataType, DataType]) pandera.dtypes.DataType instance.
- **strategy** (Optional[SearchStrategy]) an optional hypothesis strategy. If specified, the pandas dtype strategy will be chained onto this strategy.
- pattern (str) regex pattern.

Return type SearchStrategy

Returns hypothesis strategy

pandera.strategies.str_startswith_strategy(pandera_dtype, strategy=None, *, string)

Strategy to generate strings that start with a specific string pattern.

Parameters

- pandera_dtype (Union[DataType, DataType]) pandera.dtypes.DataType instance.
- **strategy** (Optional[SearchStrategy]) an optional hypothesis strategy. If specified, the pandas dtype strategy will be chained onto this strategy.
- **string** (str) string pattern.

Return type SearchStrategy

Returns hypothesis strategy

pandera.strategies.to_numpy_dtype(pandera dtype)

Convert a *DataType* to numpy dtype compatible with hypothesis.

pandera.strategies.verify_dtype(pandera_dtype, schema_type, name)

Verify that pandera_dtype argument is not None.

7.15.8 Extensions

pandera.extensions

pandera API extensions

7.15.8.1 pandera.extensions

pandera API extensions

new in 0.6.0

This module provides utilities for extending the pandera API.

class pandera.extensions.CheckType(value)

Bases: enum. Enum

Check types for registered check methods.

VECTORIZED = 1

Check applied to a Series or DataFrame

$ELEMENT_WISE = 2$

Check applied to an element of a Series or DataFrame

GROUPBY = 3

Check applied to dictionary of Series or DataFrames.

pandera.extensions.register_check_method(check_fn=None, *, statistics=None, supported_types=(<class 'pandas.core.frame.DataFrame'>, <class 'pandas.core.series.Series'>), check_type='vectorized', strategy=None)

Registers a function as a *Check* method.

See the *user guide* for more details.

Parameters

- **check_fn** check function to register. The function should take one positional argument for the object to validate and additional keyword-only arguments for the check statistics.
- **statistics** (Optional[List[str]]) list of keyword-only arguments in the check_fn, which serve as the statistics needed to serialize/de-serialize the check and generate data if a strategy function is provided.
- **supported_types** (Union[type, Tuple, List]) the pandas type(s) supported by the check function. Valid values are pd.DataFrame, pd.Series, or a list/tuple of (pa. DataFrame, pa.Series) if both types are supported.
- **check_type** (Union[*CheckType*, str]) the expected input of the check function. Valid values are *CheckType* enums or {"vectorized", "element_wise", "groupby"}. The input signature of check_fn is determined by this argument:
 - if vectorized, the first positional argument of check_fn should be one of the supported_types.
 - if element_wise, the first positional argument of check_fn should be a single scalar element in the pandas Series or DataFrame.
 - if groupby, the first positional argument of check_fn should be a dictionary mapping group names to subsets of the Series or DataFrame.

• **strategy** – data-generation strategy associated with the check function.

Returns register check function wrapper.

7.15.9 Errors

pandera.errors.SchemaError	Raised when object does not pass schema validation
	constraints.
pandera.errors.SchemaErrors	Raised when multiple schema are lazily collected into
	one error.
pandera.errors.SchemaInitError	Raised when schema initialization fails.
pandera.errors.SchemaDefinitionError	Raised when schema definition is invalid on object val-
	idation.

7.15.9.1 pandera.errors.SchemaError

Raised when object does not pass schema validation constraints.

7.15.9.2 pandera.errors.SchemaErrors

class pandera.errors.SchemaErrors(schema_errors, data)

Raised when multiple schema are lazily collected into one error.

7.15.9.3 pandera.errors.SchemalnitError

class pandera.errors.SchemaInitError

Raised when schema initialization fails.

7.15.9.4 pandera.errors.SchemaDefinitionError

class pandera.errors.SchemaDefinitionError

Raised when schema definition is invalid on object validation.

7.16 Contributing

Whether you are a novice or experienced software developer, all contributions and suggestions are welcome!

7.16.1 Getting Started

If you are looking to contribute to the *pandera* codebase, the best place to start is the GitHub "issues" tab. This is also a great place for filing bug reports and making suggestions for ways in which we can improve the code and documentation.

7.16.2 Contributing to the Codebase

The code is hosted on GitHub, so you will need to use Git to clone the project and make changes to the codebase.

First create your own fork of pandera, then clone it:

```
# replace <my-username> with your github username
git clone https://github.com/<my-username>/pandera.git
```

Once you've obtained a copy of the code, create a development environment that's separate from your existing Python environment so that you can make and test changes without compromising your own work environment.

An excellent guide on setting up python environments can be found here. Pandera offers a environment.yml to set up a conda-based environment and requirements-dev.txt for a virtualenv.

7.16.2.1 Environment Setup

7.16.2.1.1 Option 1: miniconda Setup

Install miniconda, then run:

```
conda create -n pandera-dev python=3.8 # or any python version 3.7+
conda env update -n pandera-dev -f environment.yml
conda activate pandera-dev
pip install -e .
```

7.16.2.1.2 Option 2: virtualenv Setup

```
pip install virtualenv
virtualenv .venv/pandera-dev
source .venv/pandera-dev/bin/activate
pip install -r requirements-dev.txt
pip install -e .
```

7.16.2.1.3 Run Tests

```
pytest tests
```

7.16. Contributing 225

7.16.2.1.4 Build Documentation Locally

make docs

7.16.2.1.5 Adding New Dependencies

To add new dependencies to the project, make sure to alter the *environment.yml* file. Then to sync the dependencies from the *environment.yml* file to the *requirements-dev.txt* run the following command

```
python scripts/generate_pip_deps_from_conda.py
```

Moreover to add new dependecies in setup.py, it is necessary to add it to the **_extras_require** dictionary.

7.16.2.1.6 Set up pre-commit

This project uses pre-commit to ensure that code standard checks pass locally before pushing to the remote project repo. Follow the installation instructions, then set up hooks with pre-commit install. After, black, pylint and mypy checks should be run with every commit.

Make sure everything is working correctly by running

```
pre-commit run --all
```

7.16.2.2 Making Changes

Before making changes to the codebase or documentation, create a new branch with:

```
git checkout -b <my-branch>
```

We recommend following the branch-naming convention described in Making Pull Requests.

7.16.2.3 Run the Full Test Suite Locally

Before submitting your changes for review, make sure to check that your changes do not break any tests by running:

```
# option 1: if you're working with conda (recommended)
$ make nox-conda

# option 2: if you're working with virtualenv
$ make nox
```

Option 2 assumes that you have python environments for all of the versions that pandera supports.

7.16.2.3.1 Using mamba (optional)

You can also use mamba, which is a faster implementation of miniconda, to run the nox test suite. Simply install it via conda-forge, and make nox-conda should use it under the hood.

```
$ conda install -c conda-forge mamba
$ make nox-conda
```

7.16.2.4 Project Releases

Releases are organized under milestones, which are be associated with a corresponding branch. This project uses semantic versioning, and we recommend prioritizing issues associated with the next release.

7.16.2.5 Contributing Documentation

Maybe the easiest, fastest, and most useful way to contribute to this project (and any other project) is to contribute documentation. If you find an API within the project that doesn't have an example or description, or could be clearer in its explanation, contribute yours!

You can also find issues for improving documentation under the docs label. If you have ideas for documentation improvements, you can create a new issue here

This project uses Sphinx for auto-documentation and RST syntax for docstrings. Once you have the code downloaded and you find something that is in need of some TLD, take a look at the Sphinx documentation or well-documented examples within the codebase for guidance on contributing.

You can build the html documentation by running nox -s docs. The built documentation can be found in docs/_build.

7.16.2.6 Contributing Bugfixes

Bugs are reported under the bug label, so if you find a bug create a new issue here.

7.16.2.7 Contributing Enhancements

New feature issues can be found under the enhancements label. You can request a feature by creating a new issue here.

7.16.2.8 Making Pull Requests

Once your changes are ready to be submitted, make sure to push your changes to your fork of the GitHub repo before creating a pull request. Depending on the type of issue the pull request is resolving, your pull request should merge onto the appropriate branch:

7.16. Contributing 227

7.16.2.8.1 Bugfixes

- branch naming convention: bugfix/<issue number> or bugfix/<bugfix-name>
- pull request to: dev

7.16.2.8.2 Documentation

- branch naming convention: docs/<issue number> or docs/<doc-name>
- pull request to: release/x.x.x branch if specified in the issue milestone, otherwise dev

7.16.2.8.3 Enhancements

- branch naming convention: feature/<issue number> or feature/<bugfix-name>
- pull request to: release/x.x.x branch if specified in the issue milestone, otherwise dev

We will review your changes, and might ask you to make additional changes before it is finally ready to merge. However, once it's ready, we will merge it, and you will have successfully contributed to the codebase!

7.16.2.9 Questions, Ideas, General Discussion

Head on over to the discussion section if you have questions or ideas, want to show off something that you did with pandera, or want to discuss a topic related to the project.

7.16.2.10 Dataframe Schema Style Guides

We have guidelines regarding dataframe and schema styles that are encouraged for each pull request:

• If specifying a single column DataFrame, this can be expressed as a one-liner:

```
DataFrameSchema({"col1": Column(...)})
```

• If specifying one column with multiple lines, or multiple columns:

• If specifying columns with additional arguments that fit in one line:

```
DataFrameSchema(
     {"a": Column(int, nullable=True)},
     strict=True
)
```

• If specifying columns with additional arguments that don't fit in one line:

7.16.3 Deprecation policy

This project adopts a rolling policy regarding the minimum supported version of its dependencies, based on NEP 29:

• Python: 42 months

• NumPy: 24 months

• Pandas: 18 months

This means the latest minor (X,Y) version from N months prior. Patch versions (x,y,Z) are not pinned, and only the latest available at the moment of publishing the xarray release is guaranteed to work.

7.16. Contributing 229
